Fake news is the spreading of untrue facts online or through SNS that may influence readers’ opinions, voting choices, or even, election outcomes. SNS can be used to spread fake news (Baccarella et al., 2018). Users need to be discerning about what they read and what they believe. “Although the actual effect of fake news online on voters’ decisions is still unknown, concerns over the perceived effect of fake news

online have prevailed in the US and other countries” (Jang & Kim, 2018, p. 295). Throughout history there has always been concerns with fake news, alternatively known as propaganda. “The unprecedented popularity of social media for gathering news raises a number of critical questions regarding who trusts news in social media and what sites we trust” (Warner-Soderholm et al., 2018, p. 309). Fake news could have the potential to influence political appointments and could possibly even destroy lives. Some people may not know what or who to believe anymore which may lead to mental stress.

Fear of Missing Out (FOMO)

Fear of Missing Out (FOMO) has the greatest impact on the level of fatigue experienced by users of social media (Bright & Logan, 2018). Lack of sleep can lead to various different mental health disorders. FOMO can have an adverse effect on people’s lives, as an obsession with wanting to keep up with what everyone else is doing, can lead to user fatigue and other adverse consequences. Nicholar Carr (2010) argued the point that people’s attention span has diminished as a result of engaging with the internet and all it offers. “The Shallows: what the internet is doing to our brains” by Nicholar Carr (2010) is an insightful, inspirational, and influential book. After reading this book, one reader selected to “unsubscribe” from numerous e-mail lists, while others deactivated a number of SNS accounts. “The Circle” by Dave Eggers (2013) is another book that would really make the reader consider the amount of information that is shared online, and how all the data mining conducted by organisations is affecting our privacy.

The data mining conducted by some SNS can also affect the privacy of owners and employees of these organisations. Hackers over the years have gained access to information from many organisations around the world proving that there is no way to safely protect one’s privacy. Should an organization which runs a SNS be fined by the European Union for breach of privacy rights, this fine will not bring back the privacy that has been lost to all the users.

Even if an individual is extremely cautious about their own personal information and mindful of every piece of data they share online, others, can upload personal information and images of that person without their explicit permission. This happens all the time and the effort it takes for an individual to get this content taken back down from SNSs is extensive.

In life, it is so easy to go with the flow, without even considering what effects our actions are having on our daily lives and the daily lives of loved ones. It is so easy to get drawn into engaging with online activities, that hours can pass and be lost to the user, which could have been spent engaging with friends, doing productive work, getting exercise, or focusing on things that really matter in life. Some people are so busy recording every meal and experience to post pictures online, that they are not really focusing on the moment, relaxing, and enjoying the time spent with friends. Man has inhabited this earth for years without the need for all this connectivity and lack of privacy. Perhaps one of the reasons obesity and diabetes are on the increase is because mankind now devotes so much time online due to FOMO. If only people would consider what they are missing out by spending so much time online they might then start to relax and enjoy their own life instead of trying to imitate the lives of others as portrayed online.

Social Comparisons

As a result of using SNS some people may get the impression that others posting to the same SNS are leading better lives in comparison to their own. A survey among Korean females found that social comparison was positively associated with the use of blogs, Instagram, and LinkedIn (Chae, 2018). Engagement with SNS can produce social comparison with others (Wang et al., 2018) which may result

in feelings of loneliness in others (Sutcliffe, Binder, & Dunbar, 2018), isolation, anxiety and possibly depression. Online users tend to share the highlights of their lives which may not be representative of the real lives that they are living on a day to day basis. “Those with a high social comparison orientation should limit their use of social media to avoid emotional stress” (Chae, 2018, p. 1663). One’s self esteem can be adversely affected through social comparison with others. As long as people do not realise the potential damage of engaging with SNS they may continue to suffer from social comparisons with others which could lead to mental health issues.

Stalking

Some SNS have the ability to capture a person’s current location through Internet Protocol (IP) address information, this functionality can be used to track or monitor the whereabouts of others (Baccarella et al., 2018). The fact that the location of a person can be tracked may possibly be reassuring to some, for example, parents who have given a mobile phone to a child may then be able to obtain knowledge of their whereabouts at all times. Alternatively, a person’s location may be tracked without their knowledge or permission through the use of technology, by someone who is interested in their whereabouts or someone who holds a grudge, therefore, it is an invasion of personal privacy, ethically unacceptable, and potentially a safety threat. “Studies indicate a strong correlation between high Facebook usage and jealousy in relationships; in other words, as Facebook usage increases, so does jealousy” (Warner-Soderholm et al., 2018, p. 306). Some users may get unrealistic expectations of what life should be like, based on how others portray their lives to be online, this can lead to feelings of jealousy. Some may suffer from negative body image if they compare their body to those of others as they are depicted online. Some images available online may have been photo shopped to make them appear more appealing. Jealousy in relationships can lead to serious mental problems which can only get worse if one continues to stalk others and compare themselves to others as portrayed online.

SOLUTIONS AND RECOMMENDATIONS

The dark side of engaging with SNS will continue to pose problems to society in general as long as people allow SNS to take up too much of their valuable time and influence how they feel about themselves and others. To avoid undue emotional stress, users who are susceptible to a high social comparison orientation should reduce the time spent engaging with SNS (Chae, 2018), or cease to engage with SNS altogether.

Cyberbullying has the potential for serious consequences, for example, someone may feel so bad from being a victim of cyberbullying that they may consider taking their own life by committing suicide (Cohen-Almagor, 2018), or doing something else extreme. “Suicide is a major public health problem and is the second leading cause of death in young people worldwide. Indicating a lack of adequate treatment approaches, recent data suggest a rising suicide rate” (Bailey, Rice, Robinson, Nedeljkovic, & Alvarez-Jimenez, 2018, p. 499). Government funded supports are available, for example a helpline to listen to victims and help them to deal effectively with the problem (HSE, 2018a, 2018b). Unfortunately, not all victims of online bullying are aware of these services. People of all ages can be victims of cyberbullying and government provided supports should be available to help and guide all victims about the best ways to deal with the online persecution.

SNS can be used to advertise and sell all sorts of goods, including drugs and other illegal products. Concerted efforts by law enforcement agencies, the public, public health authorities, government ad-

ministrators, and technology companies will be required to successfully combat the sale of illegal drugs online (Mackey, 2018). Due to the complexities involved in dealing with cybercrimes “too few appear currently willing or able to grapple with the issues, let alone provide satisfying answers” (Slaughter, 2018, p. 118). Further research is required to determine the most productive and cost effective methods to combat cybercrimes.

Organisations’ should leverage their information security policies based on the perceived threats and benefits of employees engaging with SNS (Silic & Back, 2016). Should an employee be addicted to engaging with SNS and possibly engage during working hours, then the work that they are supposed to be doing may be neglected. Organisations’ should be aware of the perceived threats and benefits of SNS, so that they can effectively deal with these by taking appropriate action. “Fake news is a critical major issue that social networking websites can ameliorate with vigilance and skillful use of technology” (Morales, Sosa-Fey, & Farias, 2017, p. 87). Fake news poses a real challenge to society and requires further investigation.

FUTURE RESEARCH DIRECTIONS

Further research is required to determine the most productive and cost effective methods to combat cybercrimes. Law enforcement agencies and Governments have numerous challenges ahead in dealing with the dark side of SNS and cybercrime on the surface web. This is only scratching the surface as the deep and dark web are more embedded in areas where users want to hide their identity, therefore, it is much more difficult to trace the online actions of users.

Fake news has the potential to influence politics and also to destroy lives. Fake news poses a real challenge to society and requires further investigation. Members of society deserve to know the truth so that they can make informed decisions based on honest facts.

The suggestion that addiction to SNS could trigger depression in teenagers is a serious issue that deserves further research. Internet addiction is a recent and changing phenomenon (Mubarak & Quinn, 2017), which has not previously impacted on society as other addictions have done, therefore, further research is required to promote official recognition of this problem. SNS are a recent phenomenon in the history of mankind, further research is needed to ascertain the influence of addictive use of SNS on personal relationships and general well-being.

CONCLUSION

Although SNS are used by many people all around the world to connect with loved ones and friends in a positive context, alas, SNS are also used by many people in a negative context, including some of the topics discussed in this chapter. There are some dark sides or negative aspects to human engagement with SNS which may include the following: exposure to possible risks, spending too much time online, deleterious impacts, access to black market traders, untraceable cryptocurrencies, sale of drugs and firearms, child pornography, trade in exotic animals, identity theft, and money laundering.

Some concerns with users’ engagement with SNS are as follows: images going viral, internet addiction, depression in teenagers, lack of quality time to spend with friends and family, impact on work performance, physical and mental welfare, higher stress levels, lack of sleep, loneliness, isolation, anxiety, and jealousy, amongst many others.

These negative effects need to be taken seriously and appropriately addressed. Users should be encouraged to question the short and long term risks of engaging with SNS. Users of Social Networking Sites within the surface web and the deep and dark web require the support of government agencies in dealing with the inappropriate activities of other people engaging with these sites. The monetary cost of dealing with cybercrime puts a burden on Law Enforcement Agencies and Governments.

Society as a whole needs to consciously consider all of the negative effects of engagement with SNS, discuss these with friends, family, and work colleagues then try to reach a consensus on how best to address all of these issues.

KEY TERMS AND DEFINITIONS

Addiction or Addictive Behaviour: Actions which a person can no longer control. Someone may go online to send an e-mail, get distracted and remain online for several hours, and possibly forget to send the e-mail.

Child Pornography: Online sharing of content which shows the sexual exploitation of children.

Cyberbullying: A form of bullying that occurs online.

Dark Web: The dark web refers to a number of anonymously hosted websites on the deep web which are accessible by using specialized software to hide the internet protocol (IP) address.

Fear of Missing Out (FOMO): Some people are afraid to go offline in case they miss out on some exciting piece of news.

Fake News: The spreading of untrue facts online or through Social Networking Sites that may influence readers' opinions, voting choices, and election outcomes.

IP Address: IP addresses are assigned to every device that connects to the internet.

Social Comparisons: As a result of using social networking sites some people may get the impression that other users are leading better lives in comparison to their own.

Social Networking Sites: Social networking sites (SNS) enable users to interact with other people online; similar to how people may socially interact offline by sharing personal experiences, images, making plans, and so forth.

Stalking: A person's location may be tracked without their knowledge or permission through the use of technology, by someone who is interested in their whereabouts or someone who holds a grudge; therefore, it is an invasion of personal privacy, ethically unacceptable, and potentially a safety threat.

Virtual Private Network (VPN): A virtual private network (VPN) provides a means of connecting to a network within an organisation (as if you were inside the organisation) even though you are not physically present.

Cyberstalking: The New Threat on the Internet

INTRODUCTION

The phenomenon of stalking itself is as old as humankind itself. The past years and the expansion of digitalization have put the crime of stalking in a new light. A representative study from the USA, shows that one in four Americans has already been “harassed” online. (Duggan, 2017) If stalking in the traditional sense (also known as offline stalking or classic stalking) is described as obsessive harassment / threat over a longer period, it takes on a new criminal dimension as soon as connected communication takes place. New forms of crime such as cyberstalking, cyberbullying, and romance scams have now reached our everyday lives. The main objective of this article is to introduce a representative study on cyberstalking cases in Austria to the scientific community. In addition, it should provide a clearer picture of cyberstalking based on evidence-based international data.

BACKGROUND

There is no doubt that stalking is a common criminal offence that has taken on a new dimension with the expansion of the Internet. According to Pathe and Mullen (Pathe & Mullen, 1997), stalking is described as a set of behaviours in which the stalker continuously and violently penetrates the victim’s privacy and harasses the victim through personal contacts or the use of communication media. (Pathe & Mullen, 1997) Cyberstalking is often viewed as a natural continuation of offline stalking given their conceptual and operational overlap. In classical stalking one speaks of persistent persecution. This includes persecution, ambush, trespassing, and the unintentional receipt of gifts, letters and telephone calls. The development of telecommunications has brought about a change in the way the media communicate, with the result that traditional communication methods have been replaced by Internet communication.

This led to the development of new stalking methods, which found their way into encyclopaedias under the neologism of “cyberstalking”. Hoffmann defines cyberstalking as “the obsessive persecution or harassment of another person using the Internet, e-mail, an intranet or related electronic media”. (Hoffmann, 2006, p 197) The US government defines cyberstalking as “the use of the Internet, email, or other electronic communications devices to stalk another person”. (US Attorney General, 1999) In summary, ‘cyberstalking’ means stalking processes that occur with the help of new electronic communication devices, i.e. mobile phones, smartphones, laptops or other networked mobile devices. With these devices, chatting, sharing pictures and videos or transmitting voice recordings is made much easier

DOI: 10.4018/978-1-5225-9715-5.ch043

individually and in communities. The permanent availability of the service programs on these devices makes it possible to communicate at any time of the day or night, as well as anywhere else.

The most common definitions of cyberstalking can be found in legal literature. Therefore, this definitions are bound to the legislation of the respective country and can therefore hardly provide a complete overview of all facets of cyberstalking. For a pure legal assessment, it is not necessary to cover the social phenomenon cyberstalking in all its facets. Laws have the function of subsuming accurate facts of life under legal regulations and deducing legal consequences from them. We will not stick to country bound legal definitions of cyberstalking. We see it as a recent social phenomenon, which is bound to electronic communication. If we see cyberstalking primarily as abusive communicative behaviour, we can follow Forgó et al. (Forgo, 2010) and define the term cyberstalking (in narrower sense) not only as threats and coercion but also as actions, which, due to their continuity and duration, lead to an unreasonable impairment of lifestyle. In a broader sense, the term cyberstalking includes also attacks on computer systems and defamatory publications on websites, in online forums, or in social networks, but also unwelcome publication of photos. (Forgo, 2010)

These are typical classifications from classical stalking research. According to Goodno (Goodno, 2007), five factors differentiate cyberstalking from traditional stalking. First, the perpetrators who use cyberstalking as a method are much more efficient than classical delinquents are. Due to the characteristics of internet communication, the victim is immediately and more widespread harassed than in traditional stalking. Secondly, there is no physical presence required to engage in cyberstalking. Third, cyberstalkers usually remain anonymous. By combining second and third, it is therefore much easier to engage in cyberstalking. This makes it easier for cyberstalkers to assign the harassment / threat to third parties. (Goodno, 2007) Bocij (Bocij, 2006), on the other hand, assumes that cyberstalking can also lead to physical violence in a later episode. (Bocij, 2006) Whether a person perceives cyberstalking as a threat / harassment also depends on the personal sensitivity of the victim. Some people feel because of certain actions as victims some do not. If a certain behaviour is considered as cyberstalking from a legal point of view, the person who is the victim must not necessarily feel himself / herself as a stalking victim. (Huber, 2012) Therefore, cyberstalking as a social phenomenon can only be understood by applying the current social norm. The social convention under which information is communicated and shared is an important premise whether an action is regarded as cyberstalking or not. (Nissenbaum, 2004)

Who Are the Perpetrators?

Example: Jason is not happy in his job. All the suggestions he makes to his boss are ignored. Then he also receives a letter of termination. Angry and disappointed, he wants to take revenge on his boss. He spreads lies about his boss on various internet platforms such as LinkedIn and Facebook.

The scientific literature in the field of stalking and cyberstalking focuses very strongly on the psychological condition of the perpetrators. This is due to the fact that most of the studies were conducted in the clinical field, where mentally ill stalkers were examined or the data about the perpetrators were collected through victim interviews. (Mullen & Pathe, 2000) However, if we take a more detailed look at the term “perpetrator”, it has to be said that we can only speak of a “perpetrator” in a legal sense when the person in question was sentenced by a court of law. Up to this point, we should call them suspects or strong suspects. The literature distinguishes five different types of perpetrators from classical stalking research: 1. The rejected stalker: often they are former partners of the victim. Violent acts are common in this type of stalker. In addition, personality disorders are often diagnosed. 2. The intimacy seeker: the typical cases of “erotomania” fall under this category. A typical example of this is that the stalker is often

in love with a celebrity. Violent actions rarely occur. 3. The social incompetent: this type of stalker often does not understand or misinterpret the victim's rejection due to lack of social skills. In many cases, the stalker is less intelligent or has social deficits. Violent actions are rare. 4. The revenge addict: this type of stalker feels misunderstood and goes on a personal revenge campaign, e.g. against a former boss. A paranoid clinical picture is a conspicuous component. 5. Sexual delinquents: In these cases, stalking is often the preliminary stage to a sexual offence. Often there is a predisposition and previous convictions. (Mullen PE, Pathe M, 2000) Bocij noted that cyberstalking offenders very often seek allies to stalk the victim together. He distinguishes three levels of computer education among the victims: novice, intermediate and expert. It was found that newcomers feel more threatened than experts do. On the other hand, the experts found more attacks on their PCs than people with average computer skills did. This suggests a connection between computer skills and cyberstalking behaviour. (Paul & Leroy, 2002) In another study by (Storey, J.E. & Hart, S.D., 2011), a stalker profile (not only the cyberstalker profile) was examined in Canada. Most of the perpetrators were male ($n=29$, 91%). The median age was 42 years and the most were single. Only 13,41% were unemployed and had a history of treatment for mental health problems ($n=10$, 31%). The literature knows different clinical patterns about stalking perpetrators. by (Storey, J.E. & Hart, S.D., 2011). At the psychopathological level of this multi-axial classification, 3 categories are distinguished: 1. psychotic stalkers, 2. progressive psychopathological development, and 3. Stalkers without relevant psychiatric disorder. (Dressing, H. & Foerster 2010) drivers for cyberstalking are different to the ones just discussed for classical stalking. Tokunaga, R. S., & Aune, K. S. summarize the following four motives. (Tokunaga, R. S., & Aune, K. S. 2017). 1) Hyperintimacy involves messages delivered electronically or digitally in relentless pursuit of a relationship. (Spitzberg & Hoobler, 2002). Hyperintimate messages are generally harmless but nonetheless considered as a form of harassment. 2) Threat messages in online relational pursuit involve implicit or explicit claims of bringing harm to the victim. Threats of harm can range from damaging one's reputation to more sinister acts of bodily injury. (Spitzberg & Hoobler, 2002) 3) Sabotage entails compromising targeted person's reputations by publishing either true or fabricated information about her or him. (Spitzberg & Hoobler, 2002). Typical examples are the spreading of rumors or gossip to people close to the victim. Cyberstalkers often sabotage the public image or videos of the social or professional lives of their victims. 4) Invasion is considered the most menacing set of cyberstalking behaviors because it involves many actions that profoundly interfere with the targets' livelihoods. Activities attributed to invasion can go as far as property damage and identity theft. (Spitzberg & Hoobler, 2002). Information theft and surveillance are two main types of invasion behaviors. Cyberstalkers sometimes attempt to find out and succeed in gathering private information about their victims using various means of communication technology (Bocij, 2006) (Tokunaga, R. S., & Aune, K. S. 2017)

One can say that there is no single definition of cyberstalking. This is always dependent on the legal, technical, cultural and social framework. This also results in conceptual overlaps with other phenomena such as cyberbullying, hate postings, other revenge crimes or other forms of communicative violence on the Internet. Nevertheless, the discussion about cyberstalking is more topical than ever. New challenges are emerging in sociology, justice, the police, psychology and cyber security.

In the next chapter, we will investigate further characteristics of cyberstalking offenders, based on a content analysis of court files. However, these approaches still need to be verified in the future at cyberstalking perpetrators. Now, however, there is no scientific evidence to show whether the clinical pictures of the classic stalker correspond to those of the cyberstalker. Taking a closer look to cyberstalking one of the most important questions is whether perpetrators, victims and the typical courses of events (*modus operandi*) are identical.

FOCUS OF THE ARTICLE

3

Bright Field - Dark Field

In crime, we distinguish between bright field and dark field numbers. The bright field number describes the amount of delicts that are known to the public sector as an “official” criminal offence. The dark-field-number, on the other hand, is the estimated number of unreported / undetected cases. The description of bright field and dark field data is fundamentally dependent on the respective legal and cultural situation of the country and on the methods of measurement. (Huber, 2019) In many countries, cyberstalking is not a criminal offence of its own, but is labelled as “dangerous threat / harassment” or “Cybercrime”. In methodological terms, it is always a challenge to collect the dark figures of crime. This requires a large number of long and cross-sectional studies, which are lacking for all cybercrime in general and for cyberstalking in specific. The article focusses on the phenomenon of cyberstalking solely using evidence-based data. The authors avoid the exclusive reflection in connection with classical stalking and other methodological weaknesses found in numerous studies like the limitation of the target groups, which distorts the representativeness of the results. Most studies on this or related topics are not representative, or do not exactly define the concept of cyberstalking. For example, there is a representative study on cyberbullying behaviour in the D-A-CH region (Germany, Austria, and Switzerland). (Schneider, C.; Leest, 2018) Similar to Huber’s study, this survey shows that about one third of all respondents were victims of cyberbullying. This raises the question of the extent to which individual persons can distinguish the term cyberstalking from cyberbullying. “Cyberbullying is the deliberate insulting, threatening, exposing or harassing of others with the help of Internet and mobile phone services over a longer period of time. The perpetrator - also known as a “bully” - looks for a victim who cannot or only with difficulty defend himself against the attacks. There is thus an imbalance of power between perpetrator and victim, which the perpetrator exploits, while the victim is socially isolated” (Klicksafe.de, 2018) The demarcation from cyberstalking is not easy in this case, because cyberbullying methods can also be components of cyberstalking. The difference is in long lasting, obsessive threat or harassment that affects lifestyle.

In the year 2009, Huber conducted a representative study in Austria. The aim of this research was to provide a detailed documentation and description of the cyberstalking field in Austria. This survey was the first research project that delivered reliable information on detected as well as on unreported cases. (Huber, 2012) In the process, n=747 persons aged between 18 and 66 were interviewed throughout Austria. At this time (2009), around 83% of all men and 77% of all women in Austria were online (INTEGRAL, 2010). Only for comparison currently (2018), 92% of the Austrian males and 80% of the Austrian females have internet access. (INTEGRAL, 2018) Despite of the general expansion of Internet usage, there is still a clear difference between the genders. This means that a gender gap is constantly present. Factors such as gender, income, age and education are still variables of the ‘digital divide’. In the study quoted above, the people were asked whether they have ever been stalked in their lives. In particular, stalking methods via e-mail, SMS, chat and websites - platforms such as Facebook - were in the focus of the survey. Messenger services such as WhatsApp, Snap Chat etc. were not in use in Austria at this time and therefore have not been included in the questionnaire. In this context, 34% felt harassed / threatened by e-mail stalking, 17% by SMS stalking, 6% by chat stalking and only 3% by cyberstalking on websites and platforms. This figures show that more than a third of the population has already had cyberstalking experience. Another interesting factor in this study of the unreported cases is that around 48% of the surveyed men said they had already become victims of stalking. This number differs massively from the number of reported cases. The reason for this lies in the different behaviour to take a

criminal charge between men and women. Significantly, fewer men are willing to report a cyberstalking or stalking action than women. (Huber, 2012)

Unfortunately, there are no similar representative studies on this topic to provide a global overview of the dark field. In general, we can conclude that the number of unreported cases is much higher than the number of reported cases. This difference results from various factors. On the one hand, not all cyberstalking victims report the crime. Even if the crime is reported, the deeds occur in combination with other crimes such as cybercrimes, domestic violence, harassment or dangerous threats. On the other hand, there is no clear distinction of terms worldwide, so that different cyber violent crimes, such as cyberbullying, online violence or hate postings, are often used as synonyms.

Case Study: Analysis of Court Files in Vienna (Huber & Pospisil, 2017)

As part of a research project in Vienna, a file analysis of cybercrime offences from 2006 to 2016 was carried out at the Vienna Criminal Court (Straflandesgericht Wien). The reason for the selection of the investigation period was that from 2006 onwards cybercrime cases were counted separately in the Austrian criminal statistics. Cybercrimes in its narrower meaning as well as cybercrimes in the broader sense were analysed. Based on that from 2006 ongoing distinction between traditional crime and cybercrime, around 5,408 files were available to the public prosecutor's office and the court in Vienna. A central research goal of the study was the development of reliable offender profiles and victim profiles. A sample of $n=20\%$ was drawn from $N=5,408$ court files. A quantitative document analysis according to Döllinger (Döllinger, 1984) was used as a research method for the analysis of the files. For this purpose, an analysis sheet, which contained all interesting variables, was developed. After collecting the data, a statistical analysis was executed. SPSS was used for the data analysis. Both univariate, bivariate and multivariate analysis methods were used to show the frequencies, correlations and prediction probabilities of the variables. Furthermore, cluster analysis and logistic regression were employed during the analysis process. One of the main results of the study was a catalogue of different offender profiles of cyber criminals. Based on a cluster analysis, a typologisation of cyber criminals was developed. Demographic characteristics were used as distinctive variables. The average cluster quality is 0.4, so the model is of mediocre quality. The gender variable, at 100%, was most strongly included in type formation. This is also the reason why the description of offender types is assigned to specific genders. This is followed by the education variable (52%) and the employment variable (35%). The variable age was the least taken into account in type formation (10%). Two clearly distinguishable offender types could be identified.

If we now look at the results regarding an "ideal type" in the statistical sense (more than 50%), the typical cyberstalking-defendants suspect looks like this: More than half of the suspects are male. People of this type have a low level of education. Some do not have any vocational training and have only completed primary school. Many do not have a regular job. The average age is 29.91 years (arithmetic mean). Apart of the average age of 29.91, a large part of young people up to 20 years (80%) fall into this group. In this group, most suspects have a criminal record (57%). Even though the number of cases on the problematic background is small, it should be mentioned that 64% of all persons with difficult family circumstances and 68% of all persons with addictive behaviour are of this type. An interesting feature of this type is that the suspects have no special computer skills. Their IT skills are primarily self-taught and they have good user skills.

The second type, in which cyberstalking offences have also occurred, is the group of women. The group comprises 18%. This means that about one fifth of the suspects are female. This also corresponds to the common criminal analysis of other criminal offences. The educational status is relatively differ-

ent. While half of the persons (50%) have a low level of education, a further 44% have a school-leaving certificate level. Only 6% have a high level of education. The majority of people of this type are not in regular employment, only 19% are in regular employment. This can be explained by the fact that categories such as ‘maternity leave’ or ‘pension’ can be found here. Persons of this type are on average around 32 years old (arithmetic mean). Suspects of this type are highly likely (69%) to have no criminal record and are usually not remanded in custody (81%). Women committed most of the crime (56%) as individual perpetrators. If one looks at the motives of cyberstalking suspects, it can be said that in almost all cases there was a relationship between perpetrator and victim. (Huber & Pospisil, 2017) This can be a former love relationship or an acquaintance relationship. The main motive is always revenge on a particular person.

The Unknown Perpetrator

Most delinquents therefore have a personal motive for the crime. Recent findings show us that cyberstalking is also committed by offenders who are unknown to the victims.

A current real life example of an “unknown offender” from Austria shows the following cause of events: An IT consultant, male, 55-year-old let a woman die, not really just virtually. The offender, who knew his neighbour only fleetingly, had chosen her as his victim randomly. His first action was, creating a faked Facebook profile of the woman where she offered sexual services on a professional base. The peak of the stalking activities were reached when the stalker posted a forged death certificate of the woman and reported his victim to energy suppliers and her telephone company as dead by sending e-mails to these companies pretending to be a relative. On a mourning website, the stalker published an obituary with a photo of the allegedly deceased. (n. A., 2018)

Resourceful IT-savvy people try to threaten their victims with false identities on the Internet. This pattern is often found in personal revenge or lust motifs. There does not necessarily have to be a close personal relationship or any relationship at all between perpetrator and victim. The perpetrators are IT-savvy and have the knowledge to camouflage themselves. Encryption techniques are often used to conceal the identity of the perpetrator.

Bocij (Bocij, 2006) already speaks in 2006 of the fact that there are resourceful cyber criminals who smell a business model in the field of Internet stalking and offer their services via the dark web. Current analyses by Europol (Europol, 2018) show that a new extortion method (Romance-Scams) has developed which can be considered as a version of cyberstalking. The criminal’s motives are extrinsic. They have their origin in external stimuli; their own actions are seen as building blocks for the achievement of an external goal, such as earning money. (McClelland, 1987) In such a situation, there is no connection between perpetrator and victim normally. These perpetrators also often act in groups and mask their actions.

Who Are Victims?

Example: 22-year-old Susan is separating from her boyfriend Peter. He cannot cope with the breakup. After the initial sadness about the loss, Peter becomes more and more angry. He wants to take revenge on Susan. In his revenge plans, he wants to inflict special damage and so he decides to disturb Susan’s digital life. Since Susan and Peter had a common PC, he knows the login information of Susan’s social media platforms and e-mail accounts. In no time, he has changed all their passwords so that Susan has no access to her e-mails or social media accounts. He now uses her accounts and posts obscene images of her.

When the phenomenon of stalking began to be addressed at the beginning of the 1990s, it was assumed that the stalking problem almost exclusively affected prominent people, such as Hollywood stars. Shortly afterwards, stalking victims were also discovered among the average population. (Dressing, Kuehner, & Gass, 2005) Stalking itself is a worldwide phenomenon and occurs in all cultural contexts. The spread of cyberstalking, on the other hand, depends on digitisation and broadband rollout in the respective countries. Various studies have shown that in cases of offline stalking, mainly women are the victims (90%). Numerous researches have shown that most women are victims of domestic violence in combination with stalking. (Dressing, Kühner, & Gass, 2007) (Mullen & Pathe, 2000) (McFarlane & Bocij, 2003) However, the question is, is it different with cyberstalking victims? If one analyses the victimization of cyberstalking, one is confronted relatively quickly with the problem that the person concerned has to prove (in a legal sense) that she/he has become a victim. If one orients oneself towards the traditional concept of stalking, the victim must prove that he or she has been harassed or threatened over a longer period of time, so that his or her lifestyle has been impaired. (Huber, 2012) Unfortunately, the psychological component is often ignored in this definition. The fact whether someone sees themselves as cyberstalking victims depends on the personal attitude of the victims. Some people do not mind receiving 70 WhatsApp messages a day. Others feel harassed or threatened by three messages. Referring to the above mentioned file analysis at the Vienna Criminal Court; no significant differences could be identified among the cyberstalking victims. However, one can tend to say that if the perpetrator and the victim were previously in a love relationship, there is a greater probability that the victim is a woman. On statistical average, women and men are equally likely to become victims of cyberstalking (Huber & Pospisil, 2017) As technology develops, cyberstalking victims become older. While the average cyberstalking victim in 2009 was around 35 years old (Huber, 2012), there are now younger and older victims. Bocij interviewed 169 Internet users about cyberstalking behaviour. He concentrated on the experiences of the victims. (Perpetrators themselves were not interviewed.) Over 80% had already had experience with cyberstalking, 21.9% confirmed credibly that they had been victims of cyberstalking for a longer time. (McFarlane & Bocij, 2003)

The consequences for the victims are disastrous. Victims suffer from trauma symptoms such as tension, sadness, anxiety, panic, insomnia, distrust and fear of men/women, and even post-traumatic stress disorder. (Sheridan, 2010) The literature knows of psychological damage from stalking behaviour, whether performed offline or online. It should not be forgotten, however, that the victims could also be expected to suffer financial damage. On the one hand, affected accounts have to be restored; sometimes the victim has to obtain a completely new digital identity and not to forget the costs that could result from a possible court hearing.

Nevertheless, many victims underestimate the consequences and do not report the crime. There can be different reasons for this. When cyberstalking occurs out of a past or current relationship, victims have an inhibition to report the crime to an authority. According to Huber (Huber, 2012), a maximum of 10% of cyberstalking victims are willing to report the crime. This low willingness of reporting the crime has its roots in being afraid of further acts of revenge or the victims are concerned that the cyberstalking activity can develop into a form of physical violence. Another motive for not reporting the cases is that many victims have difficulties to prove persistent persecution and threats that affect their lives in a negative way. (Huber, 2012) For example, the offender can share a video about a victim just once on YouTube. This action has a wide impact and may lead to a situation where a victim feels permanently threatened. The problem is that from this single case, the victim will find it difficult to prove persistent persecution or threat that has a degenerating affect his or her life. This problem can be solved only by improving the laws that have already been implemented in some countries.

SOLUTIONS AND RECOMMENDATIONS: WHAT IS THE TYPICAL COURSE OF ACTION (MODUS OPERANDI)?

Based on the hypothesis that the cyberstalking motif determines the course of action, this chapter will describe the methods, techniques, and typical behaviour in the course of action. With increasing digitalization, the modes operandi have also changed. This is not a special feature when dealing with stalking and cyberstalking in concrete terms. The development of crime in the last 30 years shows an increasing digitalization and change of the modus operandi in many areas. From an investigative point of view, it is interesting which methods the offenders choose to carry out their crime. This helps the investigating authorities to more easily identify the criminals and uncover cyberstalking.

Modus Operandi From Classical Stalking to Cyberstalking Research

As already discussed in the previous chapters, classical stalking very often takes place in a family, domestic or familiar environment. (Hoffmann, 2006) (Pathe & Mullen, 1997) As a result, perpetrators usually know the everyday life of the victim well and therefore choose the method that threatens or harasses the victim the most. In a representative study, it was found that the stalking method is strongly related to the stalking motif. (Huber, 2012) In all analyzed cases, there were no significant correlations to mental illnesses.

Cyberstalking of Private Individuals from the Motif of Unfulfilled Love

A typical pattern is that the suspect makes personal contact with the victim in a first step. This occurs in more than two thirds of all cases. (Huber, 2012) This occurs in the typically known communication channel, as perpetrator and victim usually communicate with each other. Whereas about 10 years ago it was SMS, telephone calls or e-mail, now it is messenger services such as Facebook Messenger, WhatsApp, Viber or Skype. If the communication does not have the desired effect, methods that are more aggressive are used. Especially in connection with domestic violence, technical tools such as espionage apps are used. The perpetrators install these apps on the victim's smartphone. In this way, they can constantly monitor where the victim is. Developments in recent years have shown that more and more perpetrators are gaining access to IoT devices.

This can be illustrated by an example from an Austrian court case: "A married couple divides. The ex-husband cannot cope with the divorce and wants to take revenge on the ex-wife. Although he has already moved out of the shared household, he still has access to the house's Internet-based control systems. In revenge he turns the victim's heating on in the summer and the light on and off in the night. Since he also managed the systems in the marriage together, he changed the access data to this control system immediately after moving out. The wife had no choice but to file a court order for omission." (Huber & Pospisil, 2017) In this example, the perpetrator and the victim are known to each other. In many escalation scenarios of such cases, intimate photos of the ex-partner are shared on social media platforms such as Facebook and Instagram. In contrast to situations where offender and victim are / were acquainted also, a few cases of cyberstalking are known in which the offender and victim do not know each other personally. This occurs, for example, with people who are in the public eye, such as actors or politicians. In these situations, it is often the case that the perpetrator illegally obtains access data to private accounts or mobile phones and harasses the victim with messages.

Revenge - Crime: Cyberstalking Because of Revenge Motives

Cyberstalking does not always result from an unfulfilled love. In addition, personal feelings of revenge out of professional or other private contexts can end in cyberstalking. The above mentioned court file analysis of all cybercrimes cases in Austria from 2006 to 2016 has shown that 43% of all cases (reported as well as unreported) fall within the area of revenge crime. (Huber, Pospisil & Seböck, 2018)

Commercial Cyberstalkers - Romance-Scams

Romance scams are a more recent development. They are regarded as a specific version of cyberstalking. The typical course of events is as follows:

In a first step, victims are addressed by perpetrators via social media platforms. Over a longer period, the perpetrator tries to establish a virtual but personal relationship with the victim. The goal of the criminal is to get so familiar with the victim that she or he sends private photos or videos to the delinquent. If these materials contain compromising content, the criminal has what he wants. Usually, the social media profile is deleted shortly afterwards. A few days later, the victim is blackmailed. If the victim does not pay, the pictures or videos are made available to the family, the employer or the public. (Europol, 2018) These perpetrators correspond to the profile of the classic cybercriminal. They often act from abroad. They can camouflage themselves very well and always operate out of a criminal group.

FUTURE RESEARCH DIRECTIONS

In summary, it can be said that cyberstalking is still a fuzzy term. The accurate meaning of cyberstalking is dependent of the legal, cultural, technical, social or psychological perspective from which the subject is investigated. Therefore, we can identify conceptual overlaps with cyberbullying, hate postings or other communicative violence on the Internet.

In general, it can be said that the use of modern telecommunication technologies makes it for offenders easier to stay anonymous. Encryption techniques such as Tor or VPN make it easier for perpetrators to be anonymous. The perpetrators can be found in all areas of life. Besides the expansion of classical stalking into the cyber area, revenge-crime can also be found in the professional environment. In addition, cybercriminal methods, such as romance scams, have developed which use cyberstalking as a business model.

As can be seen from the above, cyberstalking can be regarded as an offence with different causes and manifestations. On the one hand, digitalisation has brought about a change in media usage behaviour, while the constant availability of networked end devices makes it easier to become a perpetrator or victim of cyberstalking. With the increasing digitalisation and spread of IoTs, more opportunities for threatening victims have been created. As previous trends in cyberstalking have shown, there are different strategies perpetrators can use to approach their victims, which also poses new challenges to cyber security. Cyberstalking perpetrators use software and hardware devices to monitor their victims (e.g. Spyware). A proper password and device protection is therefore as indispensable as comprehensive prevention work.

CONCLUSION

3

Therefore, countermeasures are very important. In order to take preventive action against cyberstalking, several dimensions have to be considered. On the one hand, cybersecurity measures have to be put in place so that one's own computer system and its access data are protected. This is especially true for private individuals, who often gullibly provide their access data to various online systems to partners or acquaintances. On the other hand, society has to deal with these social developments and the communicative violence behind it. Education in schools and the promotion of netiquette is therefore indispensable. In addition, we have to start a political discussion regarding the rapid development of technology. It should be common knowledge that private individuals should avoid posting private information publicly on social media platforms such as Facebook, WhatsApp or Instagram. Above all, sensitive data such as telephone numbers, addresses and other personal information must not be published. In addition, effective password protection for private online accounts is necessary. Passwords should also be changed at regular intervals, especially if you have separated after a partnership. To make sure that there are no pictures or videos of yourself in circulation, you should google yourself regularly. To protect yourself from professional cyberstalking, good security software is needed, in order to protect your mobile devices from spyware or hacker attacks. One of the most important things is not to show too much credulity towards unknown people you meet on the internet. Furthermore, it is important to see recognize cyberstalking as a type of cybercrime. This requires taking the cultural aspects of each country and the current standards of cyber security into account.

KEY TERMS AND DEFINITIONS

Brightfield: All criminal cases in a particular area known to the authorities.

Commerical Cyberstalker: A perpetrator who engage in cyberstalking for the purpose of financial gain.

Cyberstalking: A obsessive persecution or harassment of another person using IKT.

Darkfield: All criminal cases, in a certain area, that are not known to the authorities.

Modus Operandi: The typical course of events in a criminal offence.

Private Cyberstalker: A perpetrator of cyberstalking for personal motives.

Romance Scams: Social media are used to establish a relationship of trust between the perpetrator and the victim. As soon as the victim transmits confidential pictures or videos to the perpetrator, the perpetrator abuses them for blackmail purposes.

The Nature of Cyberbullying Among Youths

Michelle F. Wright

Penn State University, USA

INTRODUCTION

Millions of youths use electronic technologies, such as mobile phones and the Internet, daily (Lenhart, 2015). These technologies allow youths many opportunities, such as the ability to communicate with just about anyone, quick access to information for leisure and homework purposes, and entertainment (e.g., watching videos). Despite the positives associated with electronic technology use, many youths are at risk for exposure to problematic online situations. Such situations might involve viewing unwanted electronic content through videos, images, and text, which contains gory or sexually graphic content. Problematic online situations also include experiencing identity theft and being targeted by sexual predators. Cyberbullying is another risk associated with youths' electronic technology use.

Defined as an extension of traditional bullying, cyberbullying involves being targeted by negative and unwanted behaviors via electronic technologies, including email, instant messaging, social networking websites, and text messages via mobile phones (Bauman, Underwood, & Card, 2013; Grigg, 2012). The anonymity of the cyber context allows cyberbullies greater flexibility to harm their victims without having to witness the reactions of the victims and/or experience any negative consequences as a result of their actions (Wright, 2014b). Cyberbullies' ability to remain anonymous is made possible by the ability to mask or hide their identity in cyberspace. Because youths can remain anonymous online, anonymity can trigger the online disinhibition effect. The online disinhibition effect is when youths do or say something to others that they typically would never do or say in the offline world (Suler, 2004; Wright, 2014). Another component of electronic technologies is the rapid transmission of communication. Because electronic technologies have such a feature, many cyberbullies can target their victims more quickly. For example, a rumor in the offline world might take several hours to spread around school, while in the online world, this rumor could take a matter of minutes to spread to various classmates. Bullies can often target victims as often as they want as it is difficult to escape bullying in the online world as the behaviors can follow the person almost anywhere there is electronic technology access. Although it is possible to have many bystanders for traditional school bullying, cyberbullying has the potential to reach an audience of millions. These individuals can then perpetuate the cycle of cyberbullying by further sharing cyberbullying content (e.g., videos, pictures) with others.

The aim of this chapter is to review the topic of cyberbullying among youths, who might include children and adolescents from elementary school to high school. The literature reviewed includes studies from various disciplines, such as psychology, education, media studies, communication, social work, sociology, computer science, information technology, and gender studies. These studies might also include cross-sectional, longitudinal, qualitative, quantitative, and mixed-methods research designs. The chapter also draws on various studies across the world to conceptualize cyberbullying as a global health concern. The chapter includes seven sections, including:

DOI: 10.4018/978-1-5225-9715-5.ch044

1. **Background:** Contains the definition of cyberbullying, the various characteristic behaviors, the various electronic technologies, the prevalence rates of cyberbullying, and the role of anonymity in perpetrating cyberbullying.
2. **Youths' Characteristics and Risk Factors:** Reviews the factors associated with youths' involvement in cyberbullying as perpetrators and/or victims.
3. **Negative Psychosocial and Academic Outcomes:** Explains research findings regarding the psychological, social, behavioral, and academic consequences associated with youths' cyberbullying involvement.
4. **Theoretical Framework:** Provides an overview of the social cognitive theory and the online disinhibition effect, and their application to cyberbullying.
5. **Solutions and Recommendations:** This section describes suggestions for prevention and intervention programs aimed at reducing cyberbullying involvement among youths, and public policy recommendations.
6. **Future Research Directions:** Explains various recommendations for future research aimed at understanding youths' involvement in cyberbullying.
7. **Conclusion:** Highlights closing remarks regarding the current nature of the literature on cyberbullying.

BACKGROUND

Smith and colleagues (2013) defined cyberbullying as youths' use of electronic technologies to harass, embarrass, and intimidate others with hostile intent. The "hostile intent" portion of the definition is a requirement for a particular behavior or behaviors to qualify as cyberbullying. Cyberbullying can also include repetition and an imbalance of power between the perpetrator and the victim, similar to the traditional face-to-face bullying definition. In cyberbullying, the bully might target the victim multiple times by sharing a humiliating and embarrassing video or text message to one person or multiple people (Bauman et al., 2013). It might also include only sending a message to someone once. Another opportunity for repetitiveness might be sending a video or a text message to one person and then that particular person shares the content again with another person or multiple people, who then again share the content with someone else. Repetitiveness of cyberbullying captures the potentially cyclic nature of this form of bullying.

The electronic technology component of the cyberbullying definition separates this form of bullying from traditional face-to-face bullying (Curelaru, Iacob, & Abalasi, 2009). Examples of cyberbullying include sending unkind, mean, and/or nasty text messages, chat program messages, and emails, theft of identity information, pretending to be someone else, making anonymous phone calls, sharing secrets about the victim by posting or sending the secret to someone else, tricking someone to share a secret and then spreading the secret around, spreading nasty and/or untrue rumors using social networking websites, threatening to harm someone in the offline world, or uploading an embarrassing picture or video of a video who does not want the image shared (Bauman et al., 2013). Many cyberbullying behaviors are similar to those perpetrated or experienced in the offline world, such as experiencing/perpetrating harassment, insults, verbal attacks, teasing, physical threats, social exclusion, gossip, and humiliation.

Cyberbullying behaviors can occur through a variety of technologies, such as social networking websites, text messages via mobile phones, chat programs, online gaming, creation of a defamatory website against someone, and making fake social networking profiles using someone else's identity (Rideout et al., 2005). Another type of cyberbullying includes happy slapping, which involves a group of people

who insult another person at random while filming the incident via a mobile phone and then posting the images or videos online for others to watch. Flaming is another type of cyberbullying behavior, and it involves posting a provocative or offensive message in a public forum with the desire of provoking a hostile response or triggering an argument with other members of the forum. The most frequently utilized technologies to harm others include gaming consoles, instant messaging tools, and social networking websites (Ybarra et al., 2007).

The prevalence rates of cyberbullying among youths has been frequently examined. In one study, 3,767 middle school students (aged 11-14) were surveyed to examine their involvement in cyberbullying (Kowalski & Limber, 2007). Of this sample, 11% reported that they were cyberbullied at least once, 4% had bullied other youths, and 7% were involved as both perpetrator and victim. Higher prevalence rates were found by Patchin and Hinduja (2006). They found that 29% of the youths in their sample reported having experienced cyber victimization and 47% indicated that they were cyberbystanders. With an older sample of youths, grades 9th through 12th, Goebert and colleagues (2011) found that 56.1% of youths in their sample from the state of Hawaii reported that they were victims of cyberbullying. Taking into account the potential of cyberbullying experiences to extend from middle school to high school, Hinduja and Patchin (2012) surveyed youths in grades 6th through 12th. They found that 4.9% of their sample perpetrated cyberbullying in the past 30 days. Although differences in prevalence rates are the result of variations in sampling techniques and measurement techniques, it is important to understand these rates as they suggest that cyberbullying is a growing concern among children and adolescents. Cyberbullying is not just a problem localized to youths in the United States. Instead, it is a global problem with increasing evidence that cyberbullying occurs in Canada, Europe, Australia, Africa, Asia, and South America.

Cyberbullying in Canada

In comparison to cyberbullying prevalence rates in the United States, rates of youths' involvement in these behaviors is lower in Canada. In particular, Cappadocia and colleagues (2013) found that 2.1% of youths in their sample of 10th graders reported that they were perpetrators of cyberbullying, 1.9% reported being cybervictims, and 0.6% explained that they were both cyberbullies and cybervictims. Slightly higher rates were found in another sample of Canadian adolescents in the 8th through 10th grades (Bonnanno & Hymel, 2013). Bonnanno and Hymel found that 6% of their sample reported that they were cyberbullies, 5.8% reported that they were cybervictims only, and 5% indicated that they were both cyberbullies and cybervictims.

Cyberbullying in Europe

Using a sample of 22,544 Swedish youths, between the ages of 15 and 18, Laftman and colleagues (2013) found that 5% of their sample were cybervictims, 4% were cyberbullies, and 2% were both cybervictims and cyberbullies. In a slightly younger sample of Swedish adolescents, 7th through 9th graders, Beckman and colleagues (2012) found that 1.9% of their sample were cybervictims, 2.9% were classified as cyberbullies, and 0.6% were cyberbullies and cybervictims. Cyberbullying has also been documented in Ireland in a sample of 876 12 through 17 year olds (Corcoran, Connolly, & O'Moore, 2012). Rates were 6% for cyber victimization among this group of Irish youths. Italian youths typically report higher levels of cyberbullying involvement when compared to youths in Northern and Western Europe. In one study, Brighi et al. (2012) found that 12.5% of the Italian youths in their sample of 2,326, with an average age of 13.9 years, were classified as cybervictims. Similar rates have been found among German

youths. In this research, Festl and colleagues (2013) found that 13% of their sample of 276 13 through 19 year olds were classified as cyberbullies and 11% were classified as cybervictims. Olenik-Shemesh et al. (2010) found that 16.5% of their participants ($N = 242$; 13-16 year olds) were cybervictims. The rate of Israeli adolescents identified as cybervictims or witnesses of cyberbullying was 32.4% of the sample ($N = 355$; 13 to 17 year olds; Lazuras et al., 2013).

Research has also been conducted with Turkish youths. In this research, Yimaz (2011) found that 18% of the 756 7th graders in the study reported that they were victimized by cyberbullying and 6% reported that they were perpetrators of cyberbullying. Rates were much higher in Erdur-Baker's (2010) study. She found that 32% of the 276 youths, ages 14 to 18 years, in her study reported that they were cybervictims. Ayas and Horzum (2012) found that 19% of youths in the sample of 12 to 14 year olds had perpetrated cyberbullying. Slightly higher rates of cyberbullying perpetration were reported among Aricak et al.'s (2008) sample of 269 Turkish secondary school students. Of these students, 36% admitted that they had cyberbullied someone at least once.

Cyberbullying in Asia

Research on cyberbullying among Asian countries has been slower to develop than research in the United States, Canada, and Europe. In this research, Huang and Chou (2010) found that 63.4% of the 545 Taiwanese youths in their sample had witnessed cyberbullying, 34.9% were classified as cybervictims, and 20.4% were classified as cyberbullies. Jang and colleagues (2014) surveyed 3,238 Korean adolescents, with findings revealing that 43% were classified as being involved in cyberbullying. Similar rates have been found among adolescents in China, with 34.8% in one sample ($N = 1,438$) reporting that they were cyberbullies and 56.9% as cybervictims (Zhou et al., 2013). Focusing exclusively on Facebook cyberbullying, Kwan and Skoric (2013) reported that 59.4% of Singaporean adolescents in their study experienced cyber victimization through this social media website, while 56.9% perpetrated cyberbullying. In addition, Wong and colleagues (2014) found that 12.2% of adolescents in their sample ($N = 1,912$) were cybervictims and 13.1% were classified as cyberbullying perpetrators.

Cross-Cultural Differences in Cyberbullying Involvement

Research on the cross-cultural differences in cyberbullying typically classified countries according to an independent self-construal or an interdependent self-construal. To have an independent self-construal view, the self is viewed as separate from the social context. On the other hand, someone with an interdependent self-construal views themselves within the context of their society. Typically people from Western countries, like the United States, Canada, and the United Kingdom, reinforce and prime people to behave in ways aligned with an independent self-construal, while people from Eastern countries, like China, Korea, and Japan, are reinforced and primed for behavior consistently in regards to an independent self-construal. Differences in these self-construals affect people's social behaviors, particularly bullying and cyberbullying. Therefore, independent and interdependent self-construals have been used to explain these behaviors. In this research, youths from the United States typically reported higher rates of cyberbullying involvement, either as perpetrators or victims, when compared to Japanese youths (Barlett et al., 2013). Similar patterns have also been found among Austrian and Japanese youths (Strohmeier, Aoyama, Gradinger, & Toda, 2013). In other research, Chinese youths reported less cyberbullying perpetration when compared to Canadian youths (Li, 2008) but more cyberbullying victimization than Canadian youths (Li, 2006). Other research comparing East Asian youths from Canada with Canadian youths, Shapka

and Law (2013) found that East Asian youths engaged in cyberbullying more for proactive reasons (i.e., to obtain a goal), while Canadian youths reported cyberbullying perpetration for reactive reasons (i.e., response to provocation). Wright and colleagues (2015) found that Indian youths reported higher levels of cyberbullying involvement than youths from China and Japan, with Indian boys reporting the highest rates of cyberbullying involvement. Conducted in European countries, Genta and colleagues (2012) compared rates of cyberbullying perpetration among youths in Italy, Spain, and England. The findings revealed that Italian boys perpetrated more cyberbullying than boys from Spain and England.

YOUTHS' CHARACTERISTICS AND RISK FACTORS FOR CYBERBULLYING

Despite differences in the estimates of cyberbullying rates, these studies provided evidence that cyberbullying is an experience that is reported among youths. With the recognition that cyberbullying is something to be concerned about among youths, researchers began to direct their attention to the characteristics and risk factors related to youths' involvement in cyberbullying.

Age was one of the first risk factors to receive attention. Findings from this research indicated that cyberbullying victimization peaked in early adolescences and that high school adolescents were more likely to perpetrated cyberbullying (Williams & Guerra, 2007). In addition, physical forms of cyberbullying, such as hacking, also peaked in middle school but generally declined in high school. On the other hand, Wade and Beran (2011) concluded that cyberbullying involvement was highest among 9th graders in their study when compared to middle school students.

Other research has focused on gender as a predictor of youths' cyberbullying involvement. Findings from this research indicated that boys were more often the perpetrators of cyberbullying when compared to girls (Boulton et al., 2012; Li, 2007; Ybarra et al., 2007). In contrast, other research (e.g., Dehue, Bolman, & Vollink, 2008; Pornari & Wood, 2010) has revealed that girls were more often cyberbullies than boys. In some studies, girls reported that they were more often victimized by cyberbullying in comparison to boys (Hinduja & Patchin, 2007; Kowalski & Limber, 2007). Contrary to these findings, some research (e.g., Huang & Chou, 2010; Sjurso, Fandrem, & Roland, 2016) has found that boys were more often cybervictims when compared to girls. Other studies (e.g., Stoll & Block, 2015; Wright & Li, 2013b) have revealed no gender differences in youths' involvement in cyberbullying.

Researchers have also directed their attention to considering youths' offline experience of perpetrators and victims of traditional school bullying as risk factors for youths' involvement in cyberbullying. These studies have considered the role of victim and perpetrator in both the face-to-face and cyber contexts. In these studies, positive associations are found between cyberbullying perpetration and traditional face-to-face bullying perpetration, cyber victimization and traditional face-to-face victimization, and cyberbullying perpetration and traditional face-to-face victimization (Barlett & Gentile, 2012; Mitchell et al., 2007; Wright & Li, 2013a; Wright & Li, 2013b).

Another risk factor associated with youths' cyberbullying involvement is their use of electronic technology. The underlying conclusion in this research is that any exposure to electronic technology can increase youths' risk of cyberbullying. Higher use of the internet is associated positively with both the perpetration and victimization by cyber victimization (Ang, 2016; Aricak et al., 2008). Compared with nonvictims, cybervictims spend more time using instant messaging tools, email, blogging sites, and online gaming (Smith et al., 2008). A possible explanation for the connection between electronic technology use and cyberbullying involvement is the likelihood that these youths disclose more personal

information online, including geographical location (Ybarra et al., 2007). Disclosing this information puts them at risk for cyber victimization.

Internalizing problems, like depression and loneliness, as well as externalizing problems, like alcohol use, are also associated with youths' involvement in cyberbullying. To explain such relationships, researchers propose that victims' coping abilities are diminished or ineffective, which makes them vulnerable to cyberbullying (Cappadocia et al., 2013; Mitchell et al., 2007). Furthermore, Cappadocia and colleagues (2013) and Wright (in press) found that alcohol and drug use were each related positively to cyberbullying perpetration.

Researchers have also identified other variables that are linked to youths' cyberbullying involvement. Normative beliefs are the beliefs that a specific set of behavior, in this case cyberbullying, is an acceptable form of behavior. In this research, youths with higher normative beliefs concerning face-to-face bullying and cyberbullying were related positively to cyberbullying perpetration (e.g., Burton, Florell, & Wygant, 2013; Wright, 2014b). Therefore, cyberbullies believe that cyberbullying is an acceptable form of behavior to engage in. Provictim attitudes, defined as the belief that bullying is unacceptable and that defending victims is valuable, is another factor related to cyberbullying. Holding lower levels of provictim attitudes is associated positively with cyberbullying perpetration (Sevcikova, Machackova, Wright, Dedkova, & Cerna, 2015). In addition, youths with lower levels of peer attachment, less self-control, and empathy, and greater moral disengagement were each related positively to cyberbullying perpetration (e.g., Wright, Kamble, Lei, Li, Aoyama, & Shruti, 2015).

Many of the studies on the characteristics and risk factors associated with cyberbullying involvement utilize cross-sectional research designs. Consequently, it is difficult to make understand the long-term associations of these characteristics and risk factors associated with cyberbullying involvement. Fanti and colleagues (2012) conducted a longitudinal study investigating youths' exposure to violent media and their callous and unemotional traits in relation to cyberbullying involvement one year later. Findings revealed that media violence exposure related to greater cyber victimization. Perceived levels of stress from parents, peers, and academics also have a role in adolescents' perpetration of cyberbullying one year later (Wright, 2014a).

In sum, there are a variety of characteristics and risk factors that make youths vulnerable to cyberbullying. Moving away from individual-related characteristics and risk factors, other researchers have examined the role of parents, schools, and teachers in youths' cyberbullying involvement.

Parents as Risk Factors

Parenting styles are linked to youths' involvement in cyberbullying. In particular, youths who are bully-victims often have parents who utilize indifferent-uninvolved parenting styles and inconsistent monitoring of their activities increases youths' involvement in cyberbullying (Totura et al., 2009). Neglectful parenting, or sometimes referred to as indifferent-uninvolved parenting, increased youths' involvement in cyberbullying in comparison to uninvolved youths (Dehue, Bolman, Vollink, & Pouwelse, 2012). Indifferent-uninvolved parents are often emotionally distance from their children, engage in little or no supervision, show little warmth and affection toward their children, place fewer demands on their children's behaviors, might and intentionally avoid their children. Cyber victimization was also increased among children who reported that their parents engaged in authoritarian parenting styles. Authoritarian parenting style is defined as parents who have high levels of demands and low levels of responsiveness. These parents have very high expectation but they display very low levels of warmth or nurturance.

Another aspect of parenting is the use of parental monitoring. The cyber context provides another opportunity for parents to monitor their children's online activity. In this research, Mason (2008) found that 50% of the children in his study reported that their parents monitored their online activities. One study explored the differences between what parents report in terms of how often they monitor their children's online activities and how often their children reported being monitored (McQuade, Colt, & Meyer, 2009). McQuade et al. found that 93% of parents in their study reported that they set limits on their children's online activities. However, only 37% of their children reported that their parents had given them rules regarding their online activities. These findings might indicate that parents overestimate the amount of monitoring they engage in or that the strategies they do implement are ineffective. Just like in the offline world, parents have an important role in protecting their children against online risks. Additional attention should be given to how parents navigate conversations with their children about online risks and opportunities.

Other research has focused on the role of parental monitoring and parental mediation in relation to reducing youths' risk of cyberbullying involvement. Wright (2015) found that when youths reported more technology mediation by their parents they reported lower levels of cyber victimization and the associated negative adjustment difficulties. To explain these connections, Wright explains that parents who monitor their children's electronic technology use might have more opportunities to engage in discussions on the risks associated with cyberbullying involvement. Parents might also convey, during these discussions, that cyberbullying is unacceptable. Such a proposal is supported by the literature as Hinduja and Patchin (2013) and Wright (2013a) found that youths who were concerned with being punished for negative online behaviors were much less likely to perpetrate cyberbullying. One study found little support that parental monitoring was helpful for preventing cyberbullying involvement. In this study, Aoyama and colleagues (2011) did not find that parental mediation and monitoring of their children's online activities were related to their children's cyberbullying perpetration and victimization. Aoyama et al. explained that many parents lack the technological skills to effectively monitor their children's online activities, which makes it difficult for them to know when and how to intervene in these activities. Another potential explanation might be that parents implement rules for electronic technology use that they do not follow-up on. Not following through with these rules can give the impression that parents are unconcerned with appropriate online behaviors, increasing the risk of engaging in cyberbullying. Failing to enforce rules might also indicate that parents do not often update strategies as their children become more independent electronic technology users. Research findings support this proposal as many parents report that they are not sure as to what type of online activities to discuss with their children (Rosen, 2007). When parents are not sure how to talk to their children about online activities, then it might lead many parents to not discuss appropriate online behaviors with their children.

There is also some research which investigates other family characteristics in relation to youths' cyberbullying involvement. Family income, parental education, and marital status of caregivers were unrelated to youths' involvement in cyberbullying (Ybarra & Mitchell, 2004). Other research indicates that parental unemployment increased youths' risk of cyberbullying perpetration and victimization (Arslan, Savaser, Hallett, & Balci, 2012).

Schools as Risk Factors

Schools' role in monitoring and punishing youth's involvement in cyberbullying is a topic of great debate about school districts, parents, authorities, and researchers. This is because many of the cases involving cyberbullying are carried out off school groups, making it difficult for schools to be aware of such cases

(deLara, 2012; Mason, 2008). However, many incidences of cyberbullying involve youths who attend the same school, making the schools' role in handling such incidences complex. Because cyberbullies and cybervictims might attend the same school, it is possible that knowledge of a cyberbullying incidence could spread throughout the school, leading to negative interactions between youths while on school grounds. These negative interactions could disrupt the learning process.

Regardless of the extent to which cyberbullying incidences can “spill over” onto school grounds, many administrators, teachers, and school districts have very different perceptions and awareness of cyberbullying. Some of these individuals might not even perceive cyberbullying as a significant event, warranting attention (Kochenderfer-Ladd & Pelletier, 2008). It is problematic when administrators and teachers do not perceive cyberbullying as problematic because electronic technology and digital communication are embedded in the lives of the youths they teach. Furthermore, these administrators and teachers are often not likely to perceive any form of covert bullying behavior as serious and harmful as physical bullying (Sahin, 2010). They are often not likely to understand the consequences associated with relational bullying and cyberbullying. This could lead to the decision not to help youths who experience these behaviors or dealing with the situation by minimizing it. Teacher training might not properly inform teachers on how to deal with and recognize cyberbullying, making teachers' ability to intervene difficult. Cassidy et al. (2012a) found that many Canadian teachers were unfamiliar with newer technologies. Being unfamiliar with newer technologies made it difficult for these teachers to deal with cyberbullying as they were often unsure of how to respond to the incidence or of how to implement strategies to address the incident. Even when teachers were concerned with cyberbullying, their school district did not have policies and programs in place to deal with these behaviors (Cassidy, Brown, & Jackson, 2012b). This made it difficult for teachers to implement solutions and strategies.

Other research has revealed that teachers were often willing to participate in prevention programs aimed at reducing traditional face-to-face bullying but not cyberbullying prevention programs (Tangen & Campbell, 2010). This could be a product of few empirically and theoretical driven cyberbullying prevention programs or that administrators and teachers do not consider cyberbullying an important enough issue to warrant attention. Recognizing the importance of implementing policies and training programs on cyberbullying is important because youths' involvement in these behaviors has the potential to impact the learning environment (Shariff & Hoff, 2007).

Educators require training to increase their awareness of cyberbullying, with the hope of developing policies at the school level to reduce these behaviors. When teachers are more confident about their abilities and have a stronger commitment to their school, they are more likely to learn about cyberbullying, and have a greater awareness of these behaviors and knowledge to deal effectively with it (Eden et al., 2013). Such awareness and knowledge prevent children's and adolescents' cyberbullying perpetration and victimization. Furthermore, when teachers feel more confident, they intervene in cyberbullying incidences more often, which protects adolescents' from experiencing these behaviors (Elledge et al., 2013). Unfortunately, teachers' motivation for learning about cyberbullying decreases from elementary school to middle school, which is problematic as cyberbullying involvement usually increases in these years (Ybarra et al., 2007). Therefore, there is a need for educator training programs aimed at raising awareness of cyberbullying, particularly in the middle school years.

Youths' involvement in cyberbullying are less likely to perceive their school and teachers positively when compared to uninvolved youths (Bayar & Ucanok, 2012). Some youths might experience cyberbullying and fear that their classmates could be responsible. This decreases these youths' concentration on learning, thereby reducing their academic attainment and performance (Eden, Heiman, & Olenik-Shemesh, 2013). Lower school commitment and perceptions of a negative school climate increase children's and

adolescents' engagement in cyberbullying as they feel less connected to their school (Williams & Guerra, 2007). Youths' involvement in cyberbullying is linked to poor academic functioning (Wright, in press).

Peer interactions are present in both the offline and online world. Through these interactions, youths learn about the social norms dictating acceptable and unacceptable behaviors within the peer group, and consequently they engage in more of the acceptable behaviors, even if they are negative. In this line of research, cyberbullying involvement is highest among classrooms in which these behaviors are elevated (Festl et al., 2013). Something about the classroom climate might be driving the levels of cyberbullying behaviors within a particular classroom. Furthermore, believing that one's friends engaged in cyberbullying also increases youths' risk of perpetrating cyberbullying (Hinduja & Patchin, 2013). Peer contagion might potentially explain these relationships. What this means is that one's friends "spread" negative online behaviors to others within their social network (Sijtsema, Ashwin, Simona, & Gina, 2014).

Another peer-related variable associated with cyberbullying involvement is peer attachment. Peer attachment is defined as the closeness that youths feel with their same or similarly aged peers. Lower levels of peer attachment were associated positively with cyberbullying perpetration and victimization (Burton et al., 2013). When youths have poor peer attachment, they are likely to believe that their peers will not be there for them when they need it. This belief promotes negative interactions with peers. Cyberbullying involvement is higher when youths' experience peer rejection, whether perceived rejection or peer-reported rejection (Sevcikova et al., 2015; Wright & Li, 2013b). Wright and Li (2012) argue that peer rejection triggers negative emotional responses that leads to cyberbullying perpetration and victimization.

Cyberbullying perpetration might also be used to maintain and boost youths' social standing among their peer group, both online and offline. Wright (2014c) found that higher levels of perceived popularity, a reputational type of popularity in the peer group, was associated positively with cyberbullying perpetration six months later. With the prominent role of electronic technologies in youths' lives, Wright proposes that they might utilize these technologies as a tool for the promotion and maintenance of their social standing. The literature in this section suggests that it is important to consider the role of schools and peers in youths' cyberbullying involvement.

NEGATIVE PSYCHOSOCIAL AND ACADEMIC OUTCOMES THE OUTCOMES ASSOCIATED WITH YOUTHS' INVOLVEMENT IN CYBERBULLYING

Concerns with cyberbullying involvement among youths were triggered by the associated negative psychosocial and academic outcomes. A potential research for these linkages is that cyberbullying disrupts youths' emotional experiences, making them more vulnerable to negative outcomes, due to ineffective coping strategies. Cybervictims are more likely than nonvictims to report lower levels of global happiness, general school happiness, school satisfaction, family satisfaction, and self-satisfaction (Toledano, Werch, & Wiens, 2015). In addition, cybervictims report more feelings of anger, sadness, and fear in comparison to noninvolved children and adolescents (Dehue et al., 2008; Machackova, Dedkova, Sevcikova, & Cerna, 2013; Patchin & Hinduja, 2006).

Cyberbullying involvement also impacts youths' academic performance. In this literature, both cybervictims and cyberbullies are at an increased risk for difficulties at school, including academic problems, less motivation for school, poor academic performance, lower academic attainment, and more school absences (Belae & Hall, 2007; Yousef & Bellamy, 2015). Lower school functioning also relates to cyberbullying perpetration and cyber victimization (Wright, in press). Cyberbullies and cybervictims

experience the lower levels of school functioning when compared to cyberbullies, cybervictims, and uninvolved youths.

Internalizing and externalizing problems are both associated with youths' cyberbullying involvement (e.g., Mitchell, Ybarra, & Finkelhor, 2007; Patchin & Hinduja, 2006; Wright, 2014b; Ybarra, Diener-West, & Leaf, 2007). Cyberbullies and cybervictims both experience suicidal thoughts and attempt suicide more often than uninvolved youths (Bauman, Toomey, & Walker 2013). Similar results were found by Beckman and colleagues (2012). Beckman and colleagues also found that cyberbullying involvement increased youths' risk for experiencing mental health problems. Other research suggests that these youths are also at risk for psychiatric and psychosomatic problems (Sourander et al., 2010).

A limitation associated with the research on the psychosocial and behavioral consequences related to youths' cyberbullying involvement is that researchers do not account for youths' involvement in traditional face-to-face bullying. It is important to account for youths' involvement in traditional face-to-face bullying because this experience is associated with similar consequences as cyberbullying and due to the high correlation between the two (Williams & Guerra, 2007; Wright & Li, 2013b). One study accounted for traditional face-to-face bullying involvement and the findings suggested that cyberbullying perpetration and victimization might have worse psychological consequences when compared to the face-to-face bullying perpetration and victimization, after controlling for face-to-face bullying and victimization (Bonanno et al., 2013).

Given the high correlation between cyberbullying and traditional face-to-face bullying involvement, some researchers have focused on the combined effects of these experiences on youths' psychosocial and behavioral outcomes. In this research, victims of both traditional face-to-face bullying and cyberbullying reported higher levels of internalizing symptoms when compared to youths who experienced only one type of victimization (Gradinger et al., 2009; Perren et al., 2012).

The research reviewed in this section suggests that a combination of various bullying experiences, whether online or offline, exacerbates youths' experience of depression, anxiety, and loneliness. These findings indicate the importance of considering youths' involvement in various bullying behaviors to better understand the best ways to intervene.

THEORETICAL FRAMEWORKS

In this section, two theories will be presented, along with their application to cyberbullying involvement among youths. These theories include the social cognitive theory and the online disinhibition effect.

According to the social cognitive theory, parents and/or friends serve as important models of behaviors that are observed and replicated by youths (Hinduja & Patchin, 2008; Mouttapa, Valente, Gallaher, Rohrbach, & Unger, 2004). This theory has been extensively applied to youths' involvement in aggressive behaviors, including cyberbullying (Barlett & Gentile, 2012). According to Olweus (1993), children's aggressive behaviors are learned or modeled by someone who was stronger than the observer. The effects of the model on the observer depended on the observer's positive evaluation of the model. These perceptions have the potential to increase the likelihood of reducing children's inhibition for aggressive behaviors and increase aggressive acts, particularly when the model is rewarded for acting aggressively. In regard to cyberbullying, youths observe various incidences of successful cyberbullying acts (Barlett & Gentile, 2012). The more often they are exposed to these acts the greater the likelihood that they believe cyberbullying is acceptable, normative, and tolerable. The anonymity offered by the cyber context increases the chance that little or no immediate consequences occur after cyberbullying perpetration.

When youths are positively reinforced for cyberbullying behaviors, adolescents held greater positive attitudes toward these behaviors (Barlett & Gentile, 2012). These attitudes relate to future perpetration of cyberbullying behaviors (Wright & Li, 2013a; Wright & Li, 2013b).

The online disinhibition effect theory refers to the likelihood that the characteristics of the cyber context will increase the likelihood that youths engage in different ways online than they would offline (Suler, 2004). The cyber context allows people to loosen, reduce, or dismiss the typical social restrictions and inhibitions present in normal face-to-face interactions (Mason, 2008). The literature supports the premise that people behave differently in cyberspace than in the offline world. Research indicates that people are likely to be blunter when communicating with others via electronic technologies (McKenna & Bargh, 2000). In online communication, there are more misunderstanding, heightened hostility, and increase in aggressive behaviors via electronic technologies when compared to face-to-face communication. It is also possible for communications through some electronic technologies might to not see emotional reactions. Not being able to see someone's emotional reactions in cyberspace prevents people from modulating their own behaviors because they are not able to witness the consequences of their actions, like they could in the offline world (Kowalski & Limber, 2007). Cyberbullying often occurs because cyberbullies cannot witness the cybervictims' reactions nor are their many opportunities to experience social disapproval, punishment, or other consequences. Many cyberbullies recognize the ease of engaging in aggressive behaviors through electronic technologies, which could potentially lead their behaviors to become more disinhibited over time, especially when they receive positive reinforcement for their behavior and are not able to recognize the consequences of their behaviors (Hinduja & Patchin, 2010; Wright, 2014a). Deindividuation, the process of not being accountable for one's actions, also occurs as a result of the online disinhibition effect (Joinson, 1998). Being able to remain anonymous through electronic technologies reduces youths' accountability for their online interactions. Coupling the reduction of accountability with the anonymity of the cyber context, might make it easier for youths to disengage from others, leading to increases in harmful online behaviors (Wright, 2014a).

SOLUTIONS AND RECOMMENDATIONS

Cyberbullying is a public health concern, warranting attention by all members of our communities, including educators, researchers, parents, and youths themselves. It is also important for education curriculum to include digital literacy skills training and citizenship in both the online and offline worlds (Cassidy et al., 2012b). Such curriculum should also focus on the positive uses of electronic technology, building empathy for negative online interactions, self-esteem, and social skills. To also improve school climate, administrators and teachers should learn students' names, praise good behavior, and stay technologically informed and up-to-date (Hinduja & Patchin, 2012).

Schools and parents should partner to help address cyberbullying. Parents should also increase their awareness and knowledge of electronic technologies (Cassidy et al., 2012a; Diamanduros & Downs, 2011). Increasing one's knowledge of electronic technologies can help parents understand the importance of technology in their children's lives and to recognize the risk and opportunities of their children's electronic technology use. Parents can also implement more effective monitoring strategies when they are more knowledge about electronic technologies and cyberbullying. Parents are encouraged to engage in open dialogue with children about appropriate electronic technology use.

FUTURE RESEARCH DIRECTIONS

There are some noticeable future directions for research on youths' involvement in cyberbullying. Anonymity is associated with youths' perpetration of cyberbullying involvement, but little attention has been given to this topic. Future research should focus on youths' perceptions of anonymous acts online and which factors might motivate them to engage in anonymous forms of cyberbullying. This research should also examine anonymous forms of cyberbullying versus non-anonymous forms of cyberbullying to better understand the motivators underlying these behaviors. This research should also investigate whether coping strategies and psychosocial adjustment difficulties vary as a function of whether cyberbullying was anonymous or non-anonymous. Additional investigations should be undertaken to understand the long-term impact of cyberbullying involvement among youths. Intervention and prevention programs could be developed which specific consideration to the specific age group identified as at the most risk for cyberbullying involvement.

CONCLUSION

The literature in this chapter provides a firm foundation for understanding youths' involvement in cyberbullying and the next directions for intervention, prevention, public policy, and research. The review suggests that much of the earlier research on cyberbullying focused on the prevalence rates of these behaviors. Current shifts in this research has changed the focus to understanding the causes and consequences of youths' involvement in cyberbullying. Although this research is still in its early stages in comparison to the literature on traditional face-to-face bullying, many of the published studies on cyberbullying focus on individual predictors of youths' involvement in these behaviors. More consideration is needed to understand the role of parents, schools, peers, and communities in youths' cyberbullying perpetration and victimization. Follow-up research on cyberbullying is important as this negative behavior impacts many aspects of our society, potentially undermining ethical and moral values. Consequently, it is imperative that we unite and do our part to reduce children's and adolescents' involvement in cyberbullying together.

SUMMARY

The purpose of this literature review was to summarize research on cyberbullying involvement among youths by providing a description and definition, information about the characteristics and risk factors, the negative adjustment outcomes associated with the involvement in these behaviors, and theoretical frameworks. The studies reviewed in this chapter utilize cross-sectional, longitudinal, qualitative, quantitative, and mixed-methods research designs. Studies with various youths from across the world were also reviewed to shed more light on the cross-cultural research on youths' cyberbullying involvement. This cross-cultural research also provides support about youths' cyberbullying involvement being a global phenomenon.

KEY TERMS AND DEFINITIONS

3

Anonymity: The quality of being unknown or unacknowledged.

Anxiety: A mental health disorder which includes symptoms of worry, anxiety, and/or fear that are intense enough to disrupt one's daily activities.

Collectivism: A cultural value that stressed the importance of the group over individual goals and cohesion within social groups.

Cyberbullying: Children's and adolescents' usage of electronic technologies to hostilely and intentionally harass, embarrass, and intimidate others.

Empathy: The ability to understand or feel what another person is experiencing or feeling.

Externalizing Difficulties: Includes children's and adolescents' failure to control their behaviors.

Individualism: The belief that each person is more important than the needs of the whole group or society.

Loneliness: An unpleasant emotional response to isolation or lack of companionship.

Normative Belief: Beliefs about the acceptability and tolerability of a behavior.

Parental Mediation and Monitoring: The strategies that parents use to manage the relationship between their children and media.

Parenting Style: The standard strategies that parents use in their child rearing.

Peer Attachment: The internalization of the knowledge that their peers will be available and responsive.

Peer Contagion: The transmission or transfer of deviant behavior from one adolescent to another.

Provictim Attitudes: The belief that bullying is unacceptable and that defending victims is valuable.

Social Exclusion: The process involving individuals or groups of people block or deny someone from the group.

Traditional Face-to-Face Bullying: The use of strength or influence to intimidate or physically harm someone.

Internet “Death Groups” in the Online Culture

Astrakhan State University, Russia

INTRODUCTION

Human existence in the space of online / digital / e-culture and information society is becoming more diverse and attractive. The digital culture used to be limited to only leisure, arts, education, and communication; over the last 20 years, it has become an essential part of the digital economy and business, e-government and online services, without which the entire social system would be malfunctioning now. A present-day person, who lives in the Internet era, would regard any gap in the electronic environment as something undermining the very fundamentals of his/her existence. Philosophic, anthropologic, social, and existential issues of the electronic culture and the digital society have become an object of in-depth research over the last two decades; research activities concerning them are becoming increasingly urgent and topical.

Nowadays the developed countries already face the consequences of virtualization of culture and interpersonal communication. Along with improvement of living standards and significant breakthroughs in medicine, electronics, and robotics, there are new deviations related to deformation of relations between a human and the world, changing attitudes to the virtual environment and communication, and increasing human alienation in the real world. The European countries, the USA, Japan, China and Russia already face the phenomenon of “escape from reality” related to the Internet culture (dependent gamers, hikikomori, etc.). They also face an increasing number of teenage and youth suicides, outbreaks of uncontrolled aggression, withdrawal into a virtual world from the real one, and increased dependence on gadgets and online presence in virtual reality; these issues are now regarded as real threats to existence of the present-day society. Virtual communities promoting murders or suicides have become a real hazard for human life and health.

Leading academic and collegiate centers in different countries of the world have been recently dealing in studying of the influence of informatization on different socio-cultural processes. Thus the issues of the development of electronic culture are the subject matter for the scientists in the University of Milan (A. Ronchi, 2009); McLuhan Institute (Virtual Maastricht McLuhan Institute (VMMI), the Netherlands (K.H. Veltman, 2004); studying ethical and anthropological issues of the information space are the subject matter for the researchers in the International Centre for Innovation in Education (ICIE) Karlsruhe, Germany (R. Capurro, 2006); London School of Economics, department of Media and Communication (Great Britain) (L. Haddon, 2004); Centre for Computing and Social Responsibility (De Montfort University, Great Britain) (S. Rogerson, 1998); Center for the Study of the Information Society of the University of Haifa, Israel (D.R. Raban, 2009); ethical, political and legal aspects of informatization are the subject matter for L. Rocci (2012); B. J. Kallenberg (2001), C.L. Chang (2011) and others.

Issues by J. Baudrillard (1993), P. Virilio (1984), B. Heller (2012), M. Heim, (1993), B., Girard, S. Siochru (2003) and P.C. Rivoltella (2008) focused to influence of e-culture (digital culture) to the hu-

DOI: 10.4018/978-1-5225-9715-5.ch045

man values, lifestyle and worldviews. Professor of Harvard University Floridi L. conducted a study on philosophy of information and ethical issues of using information technology (2013). Professor of the London Open University A. Duff a, considered ethical issues of Internet development and addressed the issues of copyright, digital inequality and violation of the right to private life (2008). F. Schäfer (2009), E. Castronova (2005) studied existential issues and risks of the information society and development of cyberculture. These problems were also raised in our earlier studies related to existential-ethical and anthropological aspects of the electronic and media culture development.

Based on the abovementioned research findings and conclusions, let us study “the death groups” operating in the Internet (“Blue Whale”, “Wake Me Up at 4:20”, etc.), which have been attracting much attention in Russian and international social media since 2015, as they provoked teenagers to commit suicide, as well as “the Columbine communities” that promote copycat crimes at educational institutions.

Our research is based on both existential and axiological approaches, as well as on an empirical data analysis (by reviewing Internet communities and their web sites). Our research determines the risk factors and characterizes “the death groups” and “the Columbine communities” as complex social phenomena of the online culture.

History of “Death Groups”

A criminal phenomenon in the digital sphere was emergence of the so-called “death groups”, whose members are forced to commit suicide. Those groups are focused mainly on adolescents, whose minds are not still developed completely, who are susceptible to manipulation. Teenage group members make their choices unconsciously; they are guided by external manipulation and obscure mechanisms that control their will or mind. They are usually driven by a desire to experience something thrilling and extreme, which is due to their disappointment in the real life. In Russia, such online groups began to spread in the social networks in 2015-2016, which has led to a number of investigations, changes in legislation, and introduction of tougher penal measures for driving someone to suicide by doing that via the Internet in particular. Similar communities have also emerged in other countries (including Ukraine, Kazakhstan), although they have not expanded so much.

The “death groups” attracted public attention in Russia in 2015, after Rina Palenkova, a teenage girl from the Siberian city of Ussuriysk, had committed a suicide. She jumped in front of a train on November 22. Just a few minutes before her death, she posted her photo with words of farewell in the most popular social networking service in Russia – VK (VKontakte). Her photo and message quickly became an Internet meme. After Rina’s death, Philipp Lis, who was the administrator of the community named “F57”, who had an intention to gain attention, publicly acknowledged his involvement in her death, as well as in some other teenager suicides. To emphasize his role, he pointed out that there was a direct link between his group and the groups “Sea of Whales” and “Silent House”. There were eight similar groups in the social networks; those groups regarded suicide as a martyrdom, a self-sacrifice that one should glorify. According to some Internet myths, souls of those who committed suicide allegedly went to the “Silent House”. This a meme of online stalking culture denoting the lowest level of the hidden web, a special state of conscience upon reaching which it is impossible to return to the real world, where they could find freedom and peace at the level of digital rebirth. Members of the community were mentally unstable teenagers, and Philipp Lis drove them to suicide by engaging them in a game. The theme of suicide, which traditionally attracts attention of young people of a certain psychological type or in a critical situation, has become popular in social networks. A number of Internet communities began to claim that they control behavior of adolescents and drive them to suicide.

The “death groups” is the name that generally describes online communities that give children assignments in a game form, thereby driving them to suicide day by day. Those communities make their members carry out more and more difficult tasks, from scratching a picture of a whale on their arms (as it is well known, whales are able to commit suicide) to jumping from roofs of high buildings and other forms of suicide. As a result, approximately 130 children perished in Russia in 2015-2016. During this period, there were at least 1,500 groups promoting suicide in VK.

As a result of investigation of 15 children’s and teenagers’ deaths, 21-year-old Phillip Budeykin (aka Lis), who administered eight “death groups”, the most notorious of which was “Blue Whale”, was arrested on November 16, 2016. The investigation was initiated in May 2016, after several Russian mass media had released news about the so-called “death groups” — numerous communities where young people were encouraged to kill themselves. In 2017, Budeykin was found guilty and sentenced to serve a prison term for 3 years and 4 months as per Clause 110 and Part 3 of Clause 30 of the Russian Criminal Code for encouraging people to commit suicide. The investigation is still in progress in a number of Russian regions—Krasnodar, Komi, Bashkortostan, Moscow, Volgograd, Voronezh, Tula, Kemerovo, Novosibirsk, and Omsk. In 2017, the social network VK recorded over 4,000 groups that promoted suicide. According to Anna Kuznetsova, Commissioner for Children’s Rights in the Russian Federation, the number of children suicides in 2016 increased by 57% (compared with 2015). Among European countries, Russia has the largest number of teenage suicides over the recent years (Gareth, 2017).

Similar communities started to appear and gain popularity among teenagers (“F57”, “Wake Me Up at 4:20”, “Sea of Whales”, “Insider”, and “Silent House”). Their primary aim was to glorify death and suicide. The game included both online and offline modes; virtual tasks were to be performed in the real life. For instance, the “Blue Whale” game had a special algorithm of actions for a teenager to follow: 1) a teenager was to make a post on his/her web page hashtagged #I’m in the game; 2) then he/she was assigned to a supervisor who gave him/her tasks and controlled their completion; 3) if any task was not complete, the teenager was threatened that his/her family members would be injured or killed. The tasks were given on a daily basis; there were 50 of them (there is a reference to the book “50 Days before My Suicide” by S. Kramer). The first tasks implied that a teenager had to cut out a picture of a whale on his/her hand; then he/she was to take a picture of himself/herself standing on a roof edge proving that he/she really did that. After that, a teenager had to kill an animal and record a video. Most teenagers dropped out at that point. The last task was “to deliver the world from his/her existence” by committing suicide in that or that form (by jumping from a roof or in front of a train, by hanging, etc.). The average age of the “death groups” members was mainly 10 to 14 years old. To enhance the impact upon them, horrible sounds, screams, psychedelic music, videos of death penalties, and other effects were applied, especially at a particular nighttime (at 4:20 a.m.). The main memes of the “death groups” are a blue whale, a butterfly (living just one day), and a “4:20” inscription.

Many teenagers and children perceive their participation in such groups as extreme entertainment. Like everything that is forbidden and related to mystery and fear, participation in such a community resembles a game for them. Moreover, they regard the tasks that those groups set them as a quest or a mission. This mechanism aims to involve more and more members in those groups. Not all the teenagers perceive the game seriously. However, there are still new victims. The “Blue Whale” game used scenarios that are popular among teenagers in cyber games: a multi-level access system, initiation tasks, obtainment of a particular status, application of symbols and signs. However, it was not a leisure or an entertaining game; it was a destructive psychological technology, which was created by those who are competent in issues of self-destruction.

After the scandalous trial, the teenagers' suicide rate commenced to decrease, and social networks' administrators and volunteers (primarily parents of deceased children) began to ban "death groups".

However, this phenomenon has not been eliminated. Over the last several years, an information war between people who promote suicidal communities and people who oppose them has been taking place in Russia. According to the "Anti-Blue Whale. We Oppose Deaths" community project, the death groups have become increasingly popular since 2017 again; they began to perform their activities in Instagram and Telegram, since their VK pages were banned. After the notorious "Blue Whale", "Whales' Sea", "Wake Me Up at 4:20", and other groups had been banned, new communities that perform similar activities emerged. In 2017 and 2018, their would-be members posted such requests as "I want to play" or "I am looking for a supervisor". Supervisors invite new members after checking their age and making sure that they deal with a teenager or a child. The newly recruited members are requested to make a small payment (50 rubles), and the game begins. Many supervisors are former players who have passed all the game levels, except for the last one, so now they coach others. Those groups often include drug addicts; their supervisors recommend that they should take drugs not to fall asleep. It becomes more and more difficult to locate such supervisors, because they are often former game players.

Viral messages related to the "Run or Die" game, in which children were requested to cross a road in front of moving vehicles, appeared in February 2018. In January 2018, a new game, whose name is "24-Hour Disappearance", emerged; it suggested that children should leave home. This game circulated in VK. According to psychologists, information about the committed suicides spreads like a virus among young people, so it can serve as a catalyst for more and more suicides. Application of such mass mailing techniques in order to attract teenagers' attention to suicide exerts destructive influence. At the same time, we believe that if the threat is obscure and the administrators of those groups act indirectly, only via a chain of associations, in this case the priming effect takes place. It implies application of certain signs and memes, which evoke particular associations in one's mind. In its turn, it results in anxiety and self-destructive tendencies. Hence, the amendments to the Federal Law concerning immediate blocking of "the death groups", which were adopted in Russia in 2018, are a crucial step in order to stop their dissemination and neutralize their fatal impact upon their victims.

Information about the game "Blue Whale Challenge" has spread in a number of countries. Police in the USA, the UK, New Zealand, and Africa warned about its hazards in the media; it also informed students' parents at schools of its destructive nature. In particular, activities performed by "the death groups" are regarded as a reason for an increased percentage of child suicides in India since 2017 (Srivastava, 2017). In 2018, the Indian law enforcement agencies informed teachers that teenagers are profoundly interested in the "Blue Whale" game, as well as in the "Momo" game that was created for WhatsApp; the authorities highly recommended that educators should monitor children's behavior more attentively (Press Trust of India, 05/09/2018).

People who tend to join the "death groups" are exposed to the same risk as totalitarian cults' members, as their conscience is highly susceptible to external manipulation. They are usually prone to depression; they have a weak will and lack social support from their close relatives and friends. Another aggravating factor is that they go through the pubertal period, when people tend to suffer from loneliness and face misunderstandings in their relations with whom they love. A third factor contributing to a deep impact that the "death groups" exert upon their victims is teenagers' tendency to express and feel strong emotions, take risks, and experience something thrilling and risky (Cuss, 2014).

Considering the "death groups", we deal with not only ordinary suicides, but also manipulations that apply certain behavioral blueprints and psychological techniques. In fact, it is a form of hidden violence. Forced suicides, unlike free-will ones, are caused by different motives. By means of destructive

physiological techniques, victims are forced to take a fatal step. Those psychological techniques exploit specific features of adolescence, young people’s interest in death and mysticism, their high sensitivity, susceptibility to abuse and intimidation, tendency to address an adult friend (supervisor) for help and advice, and an extremely strong desire to become an adult.

The psychological factor also contributes to existence of those high-risk groups. Besides the social factor, existential vacuum and shortage of meaningful goals and values, which help a person survive even under the most unfavorable conditions, play an essential role in a young person’s joining a “death group”. The way the modern youth understands the meaning of life proves to relate to their individual manifestation in the Internet, to their personal fulfillment, welfare, entertainments, and extreme experiences that fill their lives with striking moments. Formed by advertisers, the ideology of consumerism, the digital media environment, and virtual communities, those patterns exert a decisive impact upon a young person’s worldview. Neither family and religion, nor culture and education can offer a young person who joined a risk group a positive response to the most acute question of existence: “Is life worth living?” Loss of desire to live and communicate becomes the reason for committing suicides and escaping from the real world into a parallel life. The most widely spread theme among young people in network communities is their disappointment and inability to experience positive emotions. The virtual environment deprived of real emotional bonds makes a lonely person face such existential problems that cannot be resolved where the virtual communication prevails. All this contributes to growth of pessimism, boredom, and apathy, which are definitely background factors of suicide, since life seems to have no purpose or value.

FACTORS AND RISKS

People tending to join “death groups” have a risk like the one that followers have in of totalitarian sects. This type of persons is highly susceptible to external manipulation of their consciousness. They tend to depression, frustration, they have a weak will, they lack social support of friends, positive relationships with parents. Adolescence also increases alienation and rejection of others. And finally, another important factor contributing to children joining the “death groups” is the desire for extreme sensations and risk (Cuss, 2014).

In the case of “death groups” like “Blue whales” we see not only ordinary suicides, but it is a situation with manipulations imposed by behavioral scenarios and the use of certain psychotechnics. In fact, it is a form of hidden violence. Curator of such groups used features of adolescence, interest to death questions, mystery, high sensitivity, susceptibility to abuse and intimidation, a reference point to an adult friend, the desire to be an adult, exceptionally strong. Important role in getting to a risk group caused by existential vacuum, lack of meaningful goals and values that help a person survive even under the most unfavorable conditions. Modern youth’s values focus on personal fulfillment, welfare enjoyment, entertainments and peak experiences that fill the life with striking moments. Family, religion, education can’t offer to youth from a risk group the grounds for a positive answer to the main existential question – “Is life worth living?” The loss of meaning of life and communication becomes a reason of escapism of reality to virtual lives. The most wide-spread topic among teenagers in network communities is disappointment and loss of ability to experience positive emotions. A virtual environment without real emotional bonds leaves a person one on one with existential problems that cannot be solved under conditions of prevalent virtual communication. The weakening of these factors favors growing pessimism, boredom and apathy as a background for suicide as the end of the life that has no sense or value.

Administrators of virtual «death groups» use scenario like virtual games (RPG) for motivation followers pass all the stages. They use the manipulation of behavior and consciousness, based on the characteristics of juvenile psychology, to destroy the boundaries between the game and reality, allowed and forbidden. Curators of groups romanticized death and suicide as an act of freedom under own rules.

Nowadays the electronic environment is not the only foundation for modern communication and unbelievable society integration but also the ground for both conscious and unconscious escape from social reality, new escapism manifestations, refusal from a wish to live in the real world. Virtual “death groups” are the most dangerous escapism manifestation leading to suicide as a complete refusal to live.

The digital environment creates new variants of transform communication and change sociality, existence of human but it one don't give a sense of life. Being in the digital “here and now” is becoming a new personal existential problem for subject. Freedom from reality and its objectivity can lead a human being not only to self-development and creativity but to the highest degree of loneliness and digital autism (Kuss, D.J., Griffiths, M.D., Karila, L., & Billieux, J., 2014). It can also amplify escapism and suicidal ideas typical of borderline cases and conditions.

J. Baudrillard thoroughly explored the essence of the human entry into the virtual culture. He determined the ontologic status of the simulation in terms of the formation of the “hyper-reality”, absorbing and eliminating the reality (Baudrillard, 1994). Discussing the consequences of the virtual hyper reality development, J. Baudrillard asserts that the impetuous development of the virtual will lead to implosion, i.e., blurring of the borders between the real and alternative worlds. Under condition of online culture, the object - subject relations replace subject-object ones when the things, the products created by individuals, start swallowing up their originators, manipulating them, and subordinating them to their functioning.

Real relationship with other people and own status become less important than communication in “second life” (Brey, 1999).. All the choices in virtual reality are made by milder rules, the boundaries between norms and deviations become transparent, as well as truth and lie, good and evil, game and reality. This boundlessness for a digital world is perceived as a norm which has no clear guidelines.

Person's virtual being was initially intended to be a tool, a supplement to his/her real existence; however, as far as different forms of e-communication and media culture are developed, virtual being becomes a terminal value adding “mass” to a real object like a proton. The value shift from a real sphere of the being to a virtual one also indicates changes in human essence, his/her life and environment.

The most dangerous tendencies of developed digital culture lead to the loss of traditional culture and vital world of man which have existed for thousands of years and which are now disappearing under the impact of virtualization of culture. The annihilation of traditional values, models and norms of behavior formed at the level of social groups and communities leads to the change of lifestyle of man molded by new eclectic, informative and open cultural conditions which causes a greater openness and instability of the individual himself.

Serious risks are connected with the transfer of values in virtual worlds, social networks, which complicates the real communication and the capability to solve vital problems, hence develops the destructive way of thinking and self-destructive behavior. The dangerous contents of the suicide groups are the factors that contributes strongly to the self-destructive behavior of the youth. Internet game disorder, loss of real vital emotions caused by perception of oneself and his milieu as virtual world characters can be other reasons of such behavior. Interpersonal communication is being replaced by its virtual imitation, such important spheres of relations such as love and friendship are being ejected also.

Simulation of life in virtual space with the loss of the boundaries of real and game space, normative guidelines of behavior, weakening of real communication, its replacement by virtual forms become factors of existential risk for young people. The most dangerous processes in virtual communication

are associated with deliberate manipulation of consciousness, the extreme forms of which are “death groups”. Their identification and monitoring should be part of the work of law enforcement agencies, volunteers and educators around the world, as this threat has no political boundaries.

INTRODUCTION

As technology grows, human progression flourishes. Unfortunately, related issues also increase. One of the most worrying and alarming side effect of technology is cyberbullying.

If traditional bullying can be somehow associated with an ancient and instinctual desire to compete with others for survival (Donagan, 2012), cyberbullying is more difficult to frame. Even though both phenomena are a peculiar way for perpetrators to show their superiority, cyberbullying goes further: perpetrators are not just meant to overcome the opponents, their purpose is to psychologically annihilate them.

As Donagan (2012) reports, unlike traditional bullying, cyberbullying allows the offender to mask his or her identity behind a computer. Being anonymous allows perpetrators to hurl abuses and offenses at victims without having to assist to their victim's physical reaction. This "distancing effect" leads offenders to do or say things they probably would have never said or done in presence.

Nowadays, psychology is aware that the increasing diffusion of technology (Fairburn and Patel, 2016) represents a great challenge: researchers with different backgrounds must cooperate to create a virtuous exchange "man-machine". It is fundamental that the foundations of this interaction must be solid and built following specific knowledge to make technologies useful for the human cognitive progress and for people's security (Gamberini, Chittaro, & Paternò, 2012).

DOI: 10.4018/978-1-5225-9715-5.ch046

BACKGROUND

Cyberbullying is defined by Bauman, Underwood and Card (2013) as an extension of traditional bullying that involves the typical behaviors of bullying perpetrated through the use of various technologies, electronic devices in particular (e-mail, instant messaging applications, social media etc.).

Another valuable definition is provided by Belsey (2004). Belsey (2004) defines cyberbullying as a form of violence that “involves the use of information and communication technologies such as e-mail, cell phone and pager text messages, instant messaging (IM), defamatory personal Websites, and defamatory online personal polling websites, to support deliberate, repeated, and hostile behavior by an individual or group, that is intended to harm others”.

Nowadays, cyberbullying is inducing significant socio-cultural problems and psychological disorders, which requires a rapid solution. In recent years, cyberbullying has grown and now it is getting plenty of attention due to the increasingly massive use of digital devices. According to Tokunaga (2010), 97% of young Americans are connected through the Internet, while 20-40% of young people have been victim of online bullying harassment at least once in their lifetime.

Kowalski (2014) argues that cyberbullying entails relevant psychopathological risks: victims report increased depressive symptoms (Jung et al., 2014) and social anxiety; perpetrators are more likely to show aggressive behavior, due to their lack of emotional self-regulation (Kowalski, Limber & McCord, 2018). This unconventional form of bullying towards peers is also linked to suicidal attempt among adolescents (Patchin and Hinduja, 2006). Indeed, some researches showed that certain psychological factors are crucial predictors for both being a cyberbully or a victim. As Alim (2016) reports, low self-esteem is linked to a lack of confidence in one's ability and therefore it is quite easy for a cyberbully to leverage on this to afflict the victim; depression and suicidal ideation are side effects of being a designated victim (Alim, 2016). Cyberbullying not only implies high risks for teen-agers' health (Nixon, 2014), but also substantial economic costs for the families of victims for cleaning up their children online reputation of: legal fees, safety measures, psychological counseling, public relation assistance. In a Reuters post, Amy Tannery (2016) reports that a new insurance policy has been also developed in the United States in order to mitigate the financial cyberbullying consequences.

Before deepening cyberbullying, the differences between bullying and cyberbullying will be object of discussion in order to delineate an accurate overview of the phenomenon.

TRADITIONAL BULLYING VS. CYBERBULLYING

Risks connected to cyberbullying are as damaging as those of traditional bullying. When speaking of virtual environments, the main difference is that bullies can count on further protection factors such as anonymity. As a matter of fact, the possibility of hiding personal identity triggers a *disinhibition effect* leading some kids to say things that typically they would have never said face to face (Suler, 2004). However, some research found that at least 40–50% of cyber victims know the identity of the perpetrator (Kowalski & Limber, 2007; Wolak, Mitchell, & Finkelhor, 2007).

Some people could probably say that the use of technology as a mean of oppression is the only relevant difference between cyberbullying and traditional bullying. Indeed, much has already been written on this topic. This may not be the right place to deepen it, yet a quick *excursus* can help the reader to frame and contextualize the main aspects that make cyberbullying so destructive and blasting.

Actions and Threats

In traditional bullying, peer-directed physical violence is perpetrated through acts of deliberate aggression, including beating, and directs acts of verbal insults and offences (Corcoran et al., 2015; Willard, 2005).

In cyberbullying, cyber-aggression is defined by Grigg (2010) as “intentional harm delivered by the use of electronic means to a person or a group of people irrespective of their age, who perceive(s) such acts as offensive, derogatory, harmful, or unwanted” (p. 152). Cyberbullying conveys a different kind of violence that is psychological and subtle perpetrated using texts, photos, drawings, videos, and audio messages (Willard, 2005). Willard also recognizes 7 types of cyberbullying activity (in Wright et al., 2009):

- **Flaming:** Sending angry, vulgar messages to a person or a party;
- **Harassment:** Sending messages to a person repeatedly;
- **Denigration:** Sending/posting harmful, untrue information;
- **Cyberstalking:** Using threats of harm and intimidation;
- **Impersonation:** Pretending to be another person;
- **Outing or trickery:** Tricking a person into sending embarrassing information;
- **Exclusion:** Excluding someone on purpose.

Place

Traditional bullying is perpetrated in “real world” settings in terms of time and geography (Corcoran et al., 2015). Offences are in a way “restricted” to a physical place (like school).

In cyberbullying, electronic devices know no boundaries of space and time: offences can be put in action at any place at any moment in a repetitive way (Corcoran et al., 2015). Abuse may take place where the victims feel normally safe (home, community centers, places of worship, etc.) aggravating their sense of oppression and powerlessness.

Gender

In traditional bullying, males tend to bully others and be bullied through physical threats and aggressions (Bosworth, Espelage, & Simon, 1999) while girls tend to use psychological violence through a savvy use of relations and communication (Willard, 2005).

In cyberbullying, Tokunaga (2010) reports that research on differences in gender victimization lacks in findings. Few studies found out that females are more often chosen as target of cyberbullies involving psychological torment (Stephenson & Smith, 1989). Some studies highlight that “girls inflict virtual abuse more than boys through instant messaging, online conversations, and e-mails while boys are more likely to make online threats and build websites targeting others”. (Migliore, 2003 in Keith and Martin, 2005; Willard, 2005; Beale & Hall, 2007; Kowalski & Limber, 2007; Li, 2007)

Power

In traditional bullying, power derives mainly from physical prowess and higher social skills: in face to face bullying there is a power imbalance between bullies and their victims (Willard, 2005).

While in traditional bullying power is a pretty clear concept, it is difficult to define it in the cyber world: it could be the ability to stay anonymous, or to hold greater tech skills in order to inflict offences

on a large scale (Corcoran et al., 2015). Willard (2005) reports that online communication could potentially change power balance providing victims with the possibility to retaliate.

Rationalization

Willard (2005) reports that traditional rationalizations made by “face to face” bullies include justification of morally doubtful behaviors made through a shift of responsibility: victims are accountable for making the bully start a certain (bad) behavior (“*He/she started to; he/she told me to; he/she deserves to...*”).

On the contrary, cyberbullies hide themselves behind the perception of invisibility and/or multiple online identities and personalities. They think to have a supposed right of free speech on the Internet. Moreover, they count on the absence of tangible feedback: in this way they reduce the impact of empathy and recognition of harm (Willard, 2005).

Family Dynamics

If compared to other students, bullies and victims are found to perceive their families more negatively regarding problem solving when speaking of traditional bullying (Cenkseven Önder and Yurtal, 2008). Studies in the literature show that parents of bullies have lower levels of problem solving (Loeber, & Dishion, 1984) while showing higher levels of parent conflicts and discordance (Loeber, & Dishion, 1984; Oliver, Oaks, & Hoover, 1994; Olweus, 1993). Accordingly, Willard (2005) found that parents of bullies demonstrate aggressive problem solving, lack of involvement and no limits setting.

Parents of cyberbullies tend to refuse to get involved in their children’s online activity (Willard, 2005). Often, they use the “respect for their children’s privacy” as an excuse for not checking out their kids’ Internet activities: parents do not want to ask for their children keys and password if not strictly necessary. Parents may also hide the responsibility for controlling kids behind some parental control softwares that lead to insufficient security and lack of involvement (Willard, 2005).

Bystanders

In traditional bullying, bystanders assist to acts of violence without helping the victims or ignoring them on purpose. They normally refuse to get involved and justify their inactivity by saying they were just avoiding the conflict. This reaction is often due to moral disengagement (see also Thornberg and Jungert, 2013).

While traditional bystanders have quite a passive role, cyber-bystanders are proactive and somehow crucial in cyber-based abuse: they legitimate the perpetrator by viewing, “sharing” and “liking” the offences (Corcoran et al., 2015).

Listing the differences between traditional bullying and cyberbullying highlight a key point: technology has not to be intended merely as the cause of cyberbullying, but just as a mean of diffusion. Given that, from our point of view, technology is not just where the problem takes place, but it is where the problem can be solved. As for this, different in-use systems to fight and undermine cyberbullying through digital technologies will be the object of next paragraph.

THE ANSWER OF DIGITAL TECHNOLOGIES TO CYBERBULLYING

In this section, three main reasons for which digital technologies should be used to contrast cyberbullying will be described: victims' silence, capability of reaching the most isolated people and security perceived.

Silence is one of the main issues of this phenomenon due to the fact that the target is predominantly young people. Adolescents are often not mature enough to look for the proper solutions and this increases their feelings of loneliness (Şahin, 2012; Olenik-Shemesh, Heiman & Eden, 2012; Brewer & Kerslake, 2015).

As reported by many studies, most cyber victims do not inform adults about what is happening to them (Yilmaz, 2011; Agatston, Kowalski, Limber, 2012). This is a real problem because the main coping strategies for victims of cyberbullying include telling someone, keeping the situation secret, getting revenge or retirement (Nixon, 2014). It is clear that the only response strategy that doesn't compromise social relationships refers to talking with someone (Nixon, 2014).

Moreover, even if victims tell someone what is happening, adults or authorities are rarely chosen as informants. An analysis by Slonje and Smith (2008) illustrates the types of people chosen by the victims in which to confide their cyber persecution: the majority (50%) don't tell anyone, a large group (35,7%) told a friend, a smaller portion (8,9%) told a parent or guardian and the remaining subjects (5,4%) told someone else.

The diffused silence about the phenomenon requires the capability of authorities and psychologists to find out the best instruments to discover cyberbullying situations. Being able to reach individuals who are cut off from their peers can be the first step in fighting these types of events.

It must be noticed that one of the characteristics of cyberbullying is the lack of express and well-known authorities with the role of regulating misbehaviors on the World Wide Web (Tokunaga, 2010). In traditional bullying the regulation of social rules is undertaken by those such as educators or principals in cyberbullying these figures are absent (Holth & Keyes, 2004). For this reason, researchers and authorities must explore the technological and communicational instruments that are firstly able to discover bullying issues and secondly which make children and teen-agers aware of the existence of authorities responsible for regulating social behaviors on the Internet.

The proper use of technologies by the parents themselves could be a great precaution measure from cyberbullying: parents can carry out behaviors to protect their children from dangerous online events (Eastin, Greenberg & Hofschire, 2006; Livingstone, 2007) and/or share technological knowledge with the entire family to create open discussions concerning the proper use of Internet (Mesch, 2009). An analysis by Mesch (2009) conducted on 935 teens (from the age of 12 to 17 years) living in the United States showed that even if participation in online activities remains a risk factor for cyberbullying, educating parents and restricting access to the Internet are effective protection strategies for this type of phenomenon. In addition to parental control tools (e.g. NetNanny, Qustodio, OpenDNS FamilyShield, KidLogger, etc.), some social networks use lists of insults and offensive words to build moderation tools based on keywords (Van Hee, Jacobs, Emmery, Desmet, Lefever, Verhoeven, De Pauw, Daelemans, Hoste, 2018).

FOCUS OF THE ARTICLE

The previous sections explained the different ways in which cyberbullying, today, is a large-scale and multi-faceted phenomenon.

The authors aim to analyze this phenomenon - which takes advantage of new technologies – explaining which technological tools can be used to defeat it and how. This will be done by drawing on different disciplines and perspectives.

SOLUTIONS AND RECOMMENDATIONS

Unfortunately, the aforementioned tools are not enough to defend children from cyberbullies who often use implicit and inconspicuous strategies and language (Van Hee et al., 2018). For this reason, it is necessary to use the technology itself to further the research and to implement complex and self-learning systems which are able to detect these types of occurrences.

The research is already starting to move toward this direction: Van Hee and colleagues (2018) have proposed a machine learning method which uses a linear Support Vector Machine classifier (Cortes and Vapnik, 1995; Chang and Lin, 2011) to recognize “signals” of cyberbullying and build a detecting system for different kinds of cyberbullying and numerous roles involved. This type of system is not language dependent and it is a great example of how using technology can be the most efficient way to detect this type of phenomenon which is characterized by subtle language and multiple strategies.

Along with the aforementioned reasons, it must be remembered that the Internet is still perceived as safe for bullies and victims because it is the place where everyone (even the most isolated people) can find their own dimension given the numerous possibilities it offers. This is the reason why cyberspace itself is considered as the ideal location to deliver interventions built *ad hoc* for each individual facing a cyberbullying situation (Foody, Samara & Carlbring, 2015). Gámez-Guadix, Orue, Smith and Calvete (2013) analyzed a hypothetical temporal relationship between cyberbullying (as victim and as predator) and a problematic use of Internet. A problematic use of internet can be defined as an overwhelming preoccupation with the Internet and an incapability to govern use of the Internet, even when this has negative consequences (Young, 2011).

A longitudinal statistical model demonstrated how victims of cyberbullying show large scale improper use of internet, but this happens after becoming a cyber victim (Gámez-Guadix et al., 2013) as already indicated by other studies (Leung & Lee, 2012). It has already been demonstrated that improper use of internet is perpetuated to reduce feelings of anxiety and isolation, such as negative emotions (Caplan, 2010). This evidence suggests that victims of bullying and cyberbullying improperly use the Internet as a strategy to escape or avoid the negative feelings of victimization (Gámez-Guadix et al., 2013; Foody et al., 2015). Given this type of diffused coping strategy used by cyberbullies, offering interventions to the victims in the place where despite everything they feel safer is the most efficient and calibrated to the target strategy.

After reviewing the main cyberbullying characteristics to which Digital Psychology can be a response the next sections will look at three classes of interventions recently built in this area to address this complex issue. Moreover, these classes of intervention introduce the proposal of intervention which can be seen in the following section.

DIGITAL PSYCHOLOGY AGAINST CYBERBULLYING

Three categories of interventions made in the field of Digital Psychology are the object of this paragraph.

First, it's useful to observe the utility of a project that consists of a platform for adolescent victims of cyberbullying with the function of treatment and prevention (Jacobs, Vollink, Deuhue & Lechner, 2014). Secondly, a brief observation of social networks which already use new technologies to detect and prevent cyberbullying issues will be then discussed. Lastly, how a conversational agent can be used as a simulation of peer support for the victims will be shown (van Der Zwaan, Jonker & Dignum, 2010).

Jacobs and his colleagues (2014) developed a web-based intervention, *Online Pestkoppenstoppen*, with the aim of teaching cyberbullying victims, 12 to 15 years of age, to deal with anxiety and depression. It is a Platform where users can learn strategies of coping and prevention methods. The peculiarity is that in a web environment like this, learning and prevention are done in an interactive way and with the minimization of feelings of shame.

Different studies have shown that teenagers facing cyberbullying use social support as a coping strategy to a lesser extent (Dehue, Bolman & Vollink, 2008; Kowalsky, Limber & Agatston, 2008; Paris, Varjas, Meyers, Cutts, 2012). For this reason, it is necessary to find strategies that have the capacity to involve adolescents in a different way as Jacobs and colleagues (2014) did. With regard to the ways in which different adolescents can be brought in, it is very important to tailor the interventions such as building a suitable web platform (Jacobs et al., 2014).

The project made by Jacobs and colleagues (2014) represents a great starting point for this category because it teaches users efficient coping strategies through three web-based sessions regarding the importance of the awareness of our thoughts and the coping strategies to stop bullying on the web with a final session of feedback about the previous phases and the correct use of the digital tools.

The fact that each suggestion was drawn up for the personal characteristics of the participants is another positive point for the efficacy of the intervention (Jacobs et al., 2014). There are numerous studies that already show the efficacy of tailored interventions to promote changes at health behavior level (Noar, Benac & Harris, 2007; Krebs, Prochaska & Rossi, 2010; Pot, Paulussen, Ruiter, Eekhout, de Melker, Spoelstra & van Keulen, 2017) and teach coping strategies (Bock, Marcus, Pinto & Forsyth, 2001; Williams & French, 2011; Wagner, Duffecy, Penedo, Mohr & Cella, 2017) especially if associated with feedback by the experts (Jacobs et al., 2014).

What social networks are doing to face cyberbullying is of great importance and will now be explored. Facebook, in collaboration with the Yale Center for Emotional Intelligence, has built a prevention platform (*Safety Bullying* available on <https://www.facebook.com/safety/bullying>) against bullying for the different people involved (children and adolescents, parents and teachers) in this type of phenomenon. This platform provides different tips for each type of person involved and offers different examples of dialogue between the implicated people. In 2011, Facebook created a Compassion Team which is formed of researchers from Berkeley and Yale University to improve communications with people who posted improper photos of other people and the results have been positive in terms of taking down the photo or sending a reply to the requests (Anderle, 2016).

Moreover, Google (Perspective) and Instagram are providing machine learning and artificial intelligence tools to recognize the offensive comments and take the necessary precautions.

Particularly, the work that Facebook is perpetuating with its *Safety Bullying* platform is interesting because it's a first attempt to also involve bystanders in this issue. Bastiaensens, Vandebosch, Poels, Van Cleemput, DeSmet and De Bourdeaudhuij (2014) made an analysis of the bystanders' reactions to different situations that showed different types of reactions according to different variables. This study

by Bastiaensens and colleagues (2014) showed that the intentions of helping the victims increased according to the severity of the incidents but instances of joining in bullying is higher when the bullies are the bystanders' friend. Considering these types of social behaviors, precautions made by social networks are necessary to sensitize bystanders and to empower them (Davis and Nixon, 2012).

In conclusion, it is willingness of the authors describing a type of intervention that include the design of a type of embodied conversational agent (ECA) built by van Der Zwaan, Jonker and Dignum (2010). It is a simulation of peer support for cyberbullying victims that communicates in three phases with the user (emotional communication, information gathering and practical advice). Van Der Zwaan and colleagues (2010) define it as a "anti-bullying buddy" which gives child strategies to cope with negative emotions associated with the cyberbullying for facing future similar incidents. It represents a real form of empathy and social support (van Der Zwaan et al., 2010).

Embodied conversational agents can be defined as characters which are generated by computers and they are a simulation of key properties specific of human face-to-face conversation (Provoost, Lau, Ruward & Riper, 2017). This type of tool is being used for mental disorder (Provoost et al., 2017) and concerning the issue of the present article it's an example of how it could provide victims social support through new technologies such as Artificial Intelligence or Virtual Reality environments.

The importance of the perceived social support from peers is fundamental for individuals who are facing a transition (Furman and Buhrmester, 1992; Malecki and Elliot, 1999). Particularly, the importance of perceived social support was proven to be a protective factor against cyberbullying (Holt and Espelage, 2007). In this perspective, a social support simulator (van Der Zwaan et al., 2010) represents a great and controlled opportunity for situations in which real social support is lacking or it's not properly provided.

The three aforementioned categories of interventions are examples of how the scientific research community and social networks are working to face the complex phenomenon of cyberbullying through a proper use of technologies.

The next section is dedicated to the use of a new technology that can operate at an individual level with the creation of controlled environments: Virtual Reality.

FUTURE DIRECTIONS

For the future directions of the research, authors aim to deepen the role that Virtual Reality can have to prevent cyberbullying. By way of explanation of this argument, a deepening of the literature is necessary.

Virtual Reality (VR) is a tool of great potentialities because it integrates a specific communication interface in 3D interactive environment with the collecting of numerous inputs in a unique experience with a high level of similarity to reality (Riva, 2005). Besides, two peculiarities of VR are the capability of creating realism and the possibility to measure this sense of *presence* (Schuemie, van Der Straaten, Krijn & van Der Mast, 2001). This immersion gives users the possibility to have very rich experiences and to easily transfer the learnings of VR situations to the real life.

VR can operate against cyberbullying by capturing the intrinsic characteristics of the phenomenon, to implement correct real-life behavior in safe and protected environments. It allows the creation of realistic virtual environments, with a high level of control (Witmer and Singer, 1998) and security (Sahoo, Mohapatra & Lath, 2010). The VR responds to the main needs of the cyberbullying protagonists: feeling comfortable in virtual environments and the need for security.

On the other hand, it is necessary to look at the fact that bullies could use virtual reality to mistreat the victims, for example using multiplayer VR games. In 2016, the COFACE (Confederation of Family

Organization in the European Union) published a paper outlining the dangers of using VR in the most advanced video games, suggesting useful tips to mitigate their misuse.

In awareness of this danger, the authors aim to explain how virtual reality can be used as a “cure” for cyberbullying behavior, not as a tool in the bullies’ hands.

VIRTUAL REALITY AGAINST CYBERBULLYING

The VR instruments are used above all in the field of psychological intervention, especially for Post-traumatic Stress Disorder (PTSD) treatment (Rizzo, 2006). However, the scenario is currently changing, psychologists are realizing advantages and benefits of this therapy in several sectors. For example, virtual reality can be used to increase people’s empathy because of specific situations. In the past, ad hoc contexts have been developed by researchers to modulate different roles of power (Raybourn, 1999) or to recreate war environments, capable of shaking even the most convinced of war rightness (see the so called ProjectSyria).

Regarding cyberbullying and the importance of immersion for treatment, it can be useful to make a brief analysis of *FearNot!* (Fun with Empathic Agents to Reach Novel Outcomes in Teaching). *Fear!Not* is an anti-bullying intervention for children from 8 to 12 years of age (Hall, Paiva & Aylett (2009). It is not specific for cyberbullying but it can be used as structure for future more specific interventions. It was being developed for 7 years, before being included within the VICTEC (Virtual ICT with Empathic Characters) project and then in eCIRCUS (Education through Characters with emotional Intelligence and Role-playing Capabilities that Understand Social Interaction) (Hall et al., 2009). The tool provides an episodic virtual drama in which the user personifies the “invisible friend” of the character that is the victim of bullying. So, the user has the task of giving help with advice that influences the behavior of the victim and gives rise to different scenarios (Hall et al., 2009). Moreover, the results of a longitudinal evaluation showed a positive impact of *Fear!Not* on bullying in terms of information and cognizance (Sapouna, Wolke, Vannini, Watson, Woods, Schneider, Enz, Hall, Paiva & Aylett, 2010).

The great opportunity given by this type of intervention is that it provides supportive and secure learnings through experiences, moreover there is the possibility to distribute this type of intervention in the schools, to entire classrooms (Hall et al., 2009). Although, for the purposes of this article it’s important to highlight another reason for the success of the *Fear!Not* application: the social relationship created by the user with the synthetic character (Louchart, Aylett, Hall, Woods & Paiva, 2006). The realism and the social relationship created by this type of project are positive signals for the potentialities that the VR could provide to cyberbullying.

In conclusion, the authors of this article propose VR as a future instrument of response to cyberbullying for three specific reasons: VR applications can be used by numerous realities, they have the capability to deliver more efficient training about emotions and the fact that adults must be involved into this type of training can improve trust toward adults. In support of this argument, below are some examples of these conceptualizations.

An example of how VR can be wide ranging is the project built by the Harmony Labs (available on Harmony Labs.org) which presents a curriculum formed of six lessons of three-five minute VR experiences. The brevity and the availability of this type of project shows how VR can have a great impact even with brief training sessions that can be transferred to real-life situations.

The Amanda Project is a VR training tool about emotions associated with cyberbullying which was created by a group of Greek engineers for the Microsoft Imagine Cup (2016). It can be used by the us-

ers through an app and virtual reality glasses, making them live the situation of bullying both from the bystander and the victim perspectives. Then, the physical feedback changes the experiences. The creators say that the data can be used to improve awareness, empathy and self-confidence to help people answer to situations of bullying properly.

In relation to the importance of involving adults in cyberbullying phenomenon to increase their reliability for children, a prototype of training for teachers to identify bullying could be a great opportunity to create more positive societies and has already shown positive results (Stavroulia, Ruiz, Harisiou, Manouchou, Georgiou, Sella & Lanitis, 2016).

Given these results with different types of project that use VR it is necessary to further the research this direction to build specific contents and guidelines with respect to the Virtual Reality characteristics. It should be noted that VR could be the answer to cyberbullying as an instrument that can be used by qualified psychologists who are able to contextualize the emotions associated with the virtual environment compared to the real one.

To further the role of cyberbullying in different directions, being aware of different contexts in which this can be present and of the dedicated funds that are necessary. In the end, a glance at future scenarios influenced by other new technologies will be discussed.

Cyberbullying doesn't only affect children and teen-agers: nowadays, young adults and adults are also impacted by this phenomenon. A widespread use of social media is present for people of any age as can be seen by the Internet usage reports of Wearesocial and Hootsuite, published in 2018 (Lombardi, 2018): these statistics show, for example, that the major use of Facebook is by people from 18-34 years old and followed by 35-44 years olds, while those aged 13-17 years old and 46-54 years old show similar statistics.

The fact that the cyberbullying continues into adult age demonstrates a serious problem because adults better know how to operate without being charged. On the other hand, the victims can see damage not only for themselves but also for their families and their social and work life.

Cyberbullying among adults can be divided into three main categories: trolling, cyber harassment and flaming. Trolling occurs when someone creates dissension on web communities posting provocative and unrelated messages with the purpose of creating outrage among the users (Gammon, 2014). Cyber harassment is a sequence of web activities carried out by one or a group of people with the aim of provoking emotional distress in a specific victim (Bocij, 2004). Flaming is the use of messages (mostly e-mails) which show enmity, aggressiveness, and coercion in the communication with the other person (Turnage, 2008).

A study of Kircaburun and colleagues (2018) showed that there are commonalities between cyberbullies of different ages (problematic social media use and cyberbullying perpetration) and this is an additional signal that the population needs major sensibilization and research concerning this issue.

Given the positive characteristics of new technologies and of virtual reality environments, it is necessary for the institutions to start investing in creating VR environments and videogame funds. This investment must be done both in terms of treatment and prevention and sensibilization. Schools should be a context from which to start but placing funds also for adult training is of equal importance. As aforementioned, some examples of these types of positive VR environments, videogames and online communities already exist but they still are not widespread enough. A firm action by the institutions and through research is necessary. Involving technologies and new technologies in this type of work is necessary for many different reasons such as: the reproduction of realistic and involving environments, other than the clarification of the proper use of those technologies.

The progress of new technologies is a reality and a significant opportunity for the world. This must not be the opportunity for a growth in cyberbullying, as much as a way for positive development for

humanity and for detecting misuse of technologies (cf. Google Perspective, Instagram). Regarding this, Megan Meier Foundation is a positive sign of how artificial intelligence can be used to fight cyberbullying (Meier, 2018): a foundation created by a mother's victim of cyberbullying can be capable to recognize the benefit of technologies. IBM Watson technologies are being used since 2016 from Megan Meier Foundation and Identity Guard to categorize millions of messages through natural language processing (NLP) and natural language classifiers (NLC).

In conclusion, the purpose of future research must consist of clarifying the underlying psychological causes of cyberbullying and of using technology to defeat this phenomenon.

CONCLUSION

The pervasive diffusion of new technologies within new generations can be a threat or an opportunity. This different prospect relies on the research and the quality of knowledge that we will offer to new generations. The only certainty is that stopping technology is not an option nor a solution.

Once it is understood that bullying and cyberbullying are distinct phenomenon, to further research it is important to understand the distinction between them at both a theoretical and practical level. Building cohesive theories regarding cyberbullying will make researchers better able to understand this phenomenon and design well-targeted projects (Tokunaga, 2010).

Digital technologies and digital psychology have been providing different types of professional solutions in response to characteristics of cyberbullying such as silence, isolation and lack of safety perceived by the people involved. After a brief review of the psychological intervention that used platforms with tailor-made advices (Jacobs et al., 2014), social networks which provide platforms and artificial intelligence tools for prevention and the possibilities offered by an ECA in this field (van Der Zwaan et al., 2010) it is possible to have a greater understanding of how psychology and other disciplines are cooperating to build efficient solutions for cyberbullying with the available technology.

Virtual Reality (VR) can be used as treatment for all of the protagonists involved in cyberbullying (bullies, victims, bystanders, educators and parents) because it creates virtual environments with high level of realism but also control with the possibility of replicability by professional adults. This can be instrumental in increasing the trust of children and adolescents toward adults in order to build constructive relationships.

In conclusion, increasing VR research regarding cyberbullying could be the answer in terms of improving the scientific method and making projects *ad hoc* for different types of targets.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: A multidisciplinary field of research and engineering which studies the human functions that can be emulated by different types of machines.

Bullying: Arrogant attitude of people who oppress their peers through acts of physical and verbal violence. It is diffused mostly in scholar and juvenile contexts.

Cyberbullying: Attitude of overcoming from people that use informatic and web communication to denigrate their peers. It can be extended beyond physical contexts given the lack of boundaries which characterizes the world wide web.

Digital Psychology: It is a multidisciplinary (Behavioral Economics, Psychology, Digital Communication, and Information Technology) approach to psychology which integrates the study of human beings with the research on new technologies.

Embodied Conversational Agent: Characters which are generated by informatic tools and they show properties which are specific of face to face human communication.

Machine Learning: A method of data analysis based on setting automatic learning in technological tools to create analytical systems which are able to detect complex data.

Peer Support: A situational process in which respect and support principles characterize the relationships involving people with common experiences.

Virtual Reality: A virtual environment that simulates reality in which human being can be immersed through tools like glasses and visors. Depending upon different tools, the user can receive and respond to different stimuli.

Cyberbullying in the Workplace

INTRODUCTION

Technology has become the most valuable means to communicate within the contemporary workplace. The reliance on technology is increasing as it shapes the success of modern firms. Emails, messenger, cellular phones, and social media use have extended the interconnectedness among employees beyond the traditional 'brick and mortar' business environment. The advent of the internet has created a new communication tool that has, in many ways, positively revolutionized the interconnectedness of societies and business operations around the globe. As of March 2019, there is an estimated four billion, three hundred and eighty-three million internet users worldwide (Internet World Stats, 2019). In this technological age, however, there is the blurring of boundaries between personal space and workspace as the internet is a potential threat for cyber abuse, and the proliferation of the workplace stressor of cyberbullying. With the internet and modern communication devices, new forms of harassing behaviours have emerged where the target is subjected to online abusive behaviour even after leaving the workplace. Using technology to communicate may be described as a 'double-edged sword' where the increased reliance and dependence for high tech communication decreases the courteous interactions among persons. The erosive effect on interpersonal exchanges can give rise to workplace cyberbullying: an escalating process in which an employee is subjected to perceived psychological abuse recurring over a period of time where the perpetrator uses some form of technology.

For the past thirty years, organizational researchers have become increasingly interested in the dark side of management and employee behaviours, with extensive research being conducted on offline workplace bullying (henceforth referred to as traditional bullying). The increasing interest in this phenomenon has considerably advanced understanding in a relatively short space of time (Nielsen & Einarsen, 2018). Feeling trapped, frustrated, threatened, verbally abused, ignored, isolated, and mentally hurt are all common descriptors used by workers in explaining their employment situations and can be summated as 'domestic violence at work, where the abuser is on the payroll'. The issue of workplace cyberbullying is gaining increasing attention as workplace bullying is no longer confined to the traditional face-to-face work environment but has evolved with the information and communications technology (ICT) revolution. There is the alteration of the social rules that govern the workplace with the co-occurrence of traditional bullying and cyberbullying. Cyberbullying is not restrained by time, tools, or location, as 'work' is no longer a well-defined activity with sharp boundaries. The blurring of boundaries of work, technology, social media, and mobile platforms are modifying the workplace landscape. From a human resources perspective, it is therefore imperative to consider the working context within which cyberbullying occurs.

The objectives of this chapter are to:

DOI: 10.4018/978-1-5225-9715-5.ch047

- Describe the key elements of cyberbullying.
- Explain the difference between traditional bullying and cyberbullying.
- Highlight the main consequences of workplace cyberbullying on the target and on the organization.
- Suggest practical approaches organizations can adopt to prevent and address cyberbullying at work.
- Identify areas for future research on workplace cyberbullying.

BACKGROUND

The workplace has drastically been altered where employees are able to work remotely and connect with colleagues around the world. This interconnectedness is increasing the susceptibility of employees to online abusive interpersonal behaviours referred to as cyber abuse. These behaviours include cyber stalking, cyber bullying, sexual solicitation, and exposure to phonographic material (Mishna, Cook, Saini, Wu, & MacFadden, 2011). One form of cyber abuse in the workplace is ‘cyberbullying’ or ‘cyber-harassment’, by superiors, co-workers, and subordinates. Cyberbullying incorporates the use of a technological form of communication as the means through which a person is harassed, threatened, or abused. Research on cyberbullying and its consequences have focused on school children and adolescents, while the effects on adults in the workplace are now attracting the attention of scholars.

Workplace cyberbullying discussions have been generating research interests among researchers and practitioners for over the past decade, with pioneering studies exploring its conceptualization, prevalence, and consequences. While initial research on cyberbullying emerged among children (Mishna et al., 2011) there is increasing interest of cyberbullying in the workplace setting as it crosses the barrier between work and home. Scandinavian researchers first introduced the concept of ‘mobbing’ in the workplace by extending the view of children being bullied in the playground at schools to include bullying among organizational employees (Leyman 1990). Traditional bullying is a toxic event which violates the fundamental rights of workers as they are subjected to degrading and dehumanising behaviours at the hands of their perpetrator(s).

Traditional Bullying

Exposure to workplace aggression has been conceptualized by various labels such as incivility, victimization, workplace psychological harassment, social undermining, emotional abuse, mobbing, bullying, and abusive supervision. Workplace bullying is defined as “an escalating process in which one or more employees are subjected to negative psychological and physical abuse recurring over an extended period of time (usually 6 months or more), where the target is reduced to a psychologically inferior state and it creates a hostile work environment to those exposed” (Ramdeo, 2017). This form of psychological violence creates an emotionally corrosive work environment as employees struggle to determine whether bullying will continue and how it will affect their job. Traditional bullying is a form of workplace aggression which focuses on perpetrators and targets within the organization. It is necessary to consider the unique aspects of workplace bullying and workplace cyberbullying for policy development and effective management as concise differentiations would allow targets to identify and determine the nature of the behaviours. Although the literature is sparse on workplace cyberbullying, it can be concluded that engaging in these acts of aggression are motivated primarily by the intent to inflict harm and fear.

There is growing agreement among researchers regarding the noteworthy features that define workplace bullying. Firstly, the psychological imbalance that, depending on the degree of exposure, impedes the target's normal functioning. Secondly, the source of bullying, that is, the perpetrator, is someone within the organization, for instance, a supervisor, co-worker, subordinate, or group of workers. The bullying behaviours range along a continuum from subtle to extreme. Thirdly, there is the time element. For behaviour to be considered bullying there is persistent recurrence over an extended period. The perpetrator may use tactics directed to the individual and/or to the individuals work, that is, person-related bullying and/or work-related bullying (Glasø, Nielsen, & Einarsen, 2009). Person-related bullying consists of behaviours such as humiliation or ridicule in front of others, spreading malicious rumours and gossip, making insulting or offensive remarks, constant criticism, intentionally ignoring someone, direct criticism, and physical threats. Work-related bullying consists of behaviours such as excessive monitoring of work, ignoring views and opinions, assigning meaningless tasks, withholding information which can affect a worker's performance, setting unreasonable or impossible deadlines, unmanageable workloads, misuse of power or supervision (for instance, intentionally blocking promotion and/or training opportunities).

Research findings have categorized workplace antecedents or determinants at the levels of the environment, the organization, the situation, the team/group, and the person (Mathisen, Øgaard, & Einarsen, 2012). Not only is workplace bullying linked to job-related and person-related attitudes and behaviours, but also health and well-being consequences (Nielsen & Einarsen, 2012). The meta-analytic review findings by Nielsen and Einarsen (2012) identified and classified the consequences can be classified into three categories (1) job related – job satisfaction, organizational commitment, and turnover intent; (2) health-related outcomes ranging from mental health problems, physical health problems, somatization, post-traumatic stress, burnout, strain, and core self-effectiveness; and (3) behavioural outcomes – performance, and absenteeism. Furthermore, prevention (Duffy, 2009) and coping (Oade, 2009) strategies have been proposed. On the one hand, the promotion of workplace anti-bullying policies as a deterrent has also been advanced. On the other hand, the bully can deny claims being made by the target, claiming that such behaviours were for the advancement of the organization, further increasing the subjectivity surrounding bullying incidents.

A number of pre-conditions exist that triggers an individual to direct bullying actions and behaviours towards others. These include diminutive or no consequences for exhibiting such behaviours, dissatisfaction with the work environment, the power imbalance between the perpetrator and the target, and the personality of the perpetrator. Supervisory bullying (referred to as 'abusive supervision') research was championed by Tepper (2000) and is one of the most common forms of traditional bullying. The lack of status, power, or a formal process to retaliate intensifies the vulnerability of targets when the perpetrator is a supervisor.

With the increasing availability, use, and reliance on electronic technology, deepening understanding of cyberbullying and its implications for organizations should be a priority. Workplace cyberbullying involves the use of technology to bully an organizational employee. Cyberbullying, also known as electronic bullying or online social cruelty, includes the infliction of repeated and intentional harm directed towards another (Mishna et al., 2011). There are various terms that have emerged to describe this workplace phenomenon such as cyber aggression, that is, perceptions of aggression by the target (Weatherbee, 2006), and cyber incivility, that is, violations of the norms of mutual respect in the workplace (Lim & Teo, 2009). Drawing on the theoretical and empirical understandings of workplace bullying, the unique aspects of cyberbullying are explored.

FOCUS OF THE ARTICLE

3

What is Workplace Cyberbullying? The Nature and Dynamics of Cyberbullying

Through cyberspace, negative acts can include online threats, electronic harassment, cyber flashing, and electronic aggression (Farley et al. 2015). A consensus by researchers is yet to be established on whether such acts are repetitive or if it is a one-time occurrence to be classified as cyber bullying. In the work setting, the increasing use of email, text messaging, instant messaging service, social media, and phone conversations are drastically altering the communication process. The use of electronic bulletin, messaging boards, and the implementation of 360-degree performance appraisal platforms often allows employees to post anonymously, providing an avenue for virtual abuse, and more specifically, workplace cyberbullying. Furthermore, the trapped feeling experienced by the victim is intensified with the constant access via electronic devices. It is increasingly challenging as the target is unable to escape the cyberbully when at home and is unable to replenish their coping strategies. Hence, there is a new vulnerability for the victim; a disempowering effect. The victim is unable to psychologically detach from the negative acts being experienced and the violation of their dignity is intensified as compared to traditional bullying.

In establishing a workable and theoretically sound definition of workplace cyberbullying, various definitions have been proposed (Coyne et al., 2017; D'Cruz & Noronha, 2017; Langos, 2012; Vranjes, Baillien, Vandebosch, & Erreygers, 2017). These definitions include certain key elements: inappropriate and unwanted acts of hostility, intimidation, aggression and harassment with the use of ICT to carry out the bullying (for instance via email, website, cell phone, social media); a single or repeated event with the intent to harm another individual (the victim) or group of individuals; the bully can be direct (that is, in communicating with the target) or indirect (that is, posting content to forums, and on social media); the bullying is related to the work context; the persistence and intensity of the behaviours increases over time. Therefore, cyberbullying can be direct or indirect, where the perpetrator uses electronic means to taunt, harass or intimidate the target by communication via messages, pictures, and webpages to target their peers.

There are many different forms of cyberbullying tactics used by perpetrators. Some of the most common forms are as follows:

- *Harassment* is the act where malicious and offensive messages are repeatedly sent to an individual or group by the cyberbully. One form of harassment is cyberstalking where the bully makes continuous threats and sends inappropriate messages, which can manifest into real world physical harassment.
- *Flaming* is the act of posting or sending offensive messages, referred to as ‘flares’, over the internet. This usually involves an online fight where the exchange is via email, forum postings, or instant messaging. Harsh language, profanity, and images are sent to the victim by the cyberbully.
- *Exclusion* is the act where the target is intentionally left out from online/cellular phone chat groups and sites. Malicious comments are made by members of the group about the person that has been singled out. In the workplace, this may include employee chat groups and e-mail groups.
- *Outing* is the act of disseminating private and personal information, videos, and/or pictures about someone over the internet without their consent. The intent is to embarrass or publicly humiliate the target and the person is ‘outed’ when this occurs. In the workplace setting, this may include sharing information about a co-worker from their social media account with other employees who may not be a part of his/her contact listing.

- *Masquerading* is the act where a fake identity is created by the cyberbully to anonymously harass the target. Further, the cyberbully may impersonate another through masquerading to send the malicious messages to the target.
- *Denigration* is the act where an individual is criticized in a derogatory manner by the cyberbully. The intent is to defame someone's character.

Computer-mediated communication is frequently used in the business setting where misunderstandings between the sender and receiver are more likely to occur with online communication. A growing problem in the workplace is the increasing interpersonal hostility when communicating via emails. The underlying tone used to communicate is subject to misinterpretation, triggering negative work attitudes and behaviours by the recipient. Immediate clarification and feedback may be lacking due to the medium of online communication chosen. For instance, the use and intonations in the wording of emails may be perceived as offensive by the recipient since there is a lack of social cues and direct feedback. The reduced social cues or misinterpretation of emotions may explain the low empathy in online communication. Hence, the perpetrator is less aware of the target's reactions, thereby reducing the empathy towards the target and increasing the aggressive nature of the acts.

Many of the tools used by bullies to carry out cyberattacks are not exclusively available only at the workplace. Further complicating this issue is the use of company cellular phones and computers after work hours, blurring the personal boundaries of workers and increasing the difficulty to enforce codes of conduct (West, Foster, Levin, Edmison, & Robibero, 2014). Organisations. Organizations also rely heavily on social media platforms as a marketing tool to promote their products, services, and business. The use of social media tools such as Facebook Business, Twitter, and Instagram implicate the establishment of boundaries and rules on its use and pose a potential avenue for cyberbullying.

Cyberbully and Targets at Work

Cyberbullying can occur downwards, that is, by supervisor to subordinate, horizontally, that is, among co-workers, or upward, that is, subordinate to supervisor. With cyberbullying, the bully can even be a stranger within the organisation (Cruz & Noronha, 2017). Any member of the organisation is susceptible to cyberbullying. In differentiating the target and victim of cyberbullying, the target is an employee who is exposed to persistent cyberbullying behaviours. Based on self-classification, a victim is an employee who identifies as such due to the self-perception of powerlessness.

Traditional Workplace Bullying and Workplace Cyberbullying: Are they Different?

To date, there remains a lack of consensus on the conceptualization and definition of workplace cyberbullying. Earlier conceptualizations of cyberbullying have proposed that it is a form of bullying using technology as an electronic extension (Li, 2007; Privitera & Campbell, 2009). More recently, researchers have suggested that workplace cyberbullying is a distinct concept from traditional bullying (Coyne et al., 2017; Vranjes, Baillien, Vandebosch, & Erreygers, 2017). Workplace cyberbullying shares the same characteristics of traditional bullying where the negative behaviour is repeated over a period of time, and the victim is reduced to a psychologically inferior state. With cyberbullying, however, the repetition may be dependent on the technology and the features of the published content, and not limited to the

behavioural repetition of only the perpetrator, that is, direct and indirect cyberbullying (Langos 2012). The following explores some of the notable distinguishing characteristics of workplace cyberbullying.

Firstly, one key difference between traditional bullying and cyberbullying is *anonymity*. Anonymous cyberbullying can occur as a perpetrator can create a fake email or social media profiles with pseudonyms to disguise their identity. There is a greater detachment when communicating online due to the anonymity of the cyberbully. It can be argued that with traditional bullying, the bully can be identified, and the victim is able to lodge a formal complaint to the necessary organizational agents. With cyberbullying, there is a lack of restraint on what is being said about the victim. It is even more difficult for a formal complaint to be made and the organization to intervene as the victim may be unable to identify the cyberbully. Additionally, the cyberbully does not see the face of the target, thereby not understanding the full extent of the consequences of their actions and taking full responsibility, referred to as the *disinhibition effect*. The ease with which fake social media accounts can be created may allow for anonymous cyberbullying outside work hours.

Secondly, there is a *wider audience* who may be privy to the negative acts being directed to the victim than with traditional bullying. Therefore, the humiliation experienced by the cyber victim is more severe as there is the potential to spread to a limitless audience and persons may unknowingly become co-accomplices by viewing and sharing material about the victim. Social media posts and pictures can be shared without the consent of the individual being targeted.

Thirdly, digital content has a *permanent quality* where it is almost impossible to remove or delete content. Digital content can be downloaded, saved, and stored both online and offline allowing it to be retrieved at any time. Therefore, the victim is faced with the challenge of having shared material permanently remain in cyberspace which can further contribute to the psychological distress of the victim. A single incident can linger, becoming widespread and is an ongoing humiliation for the victim. Furthermore, future employers may also have access to such material when conducting background checks on job applicants.

Fourthly, in stimulating the victim's action, the *personal power* of the victim is diminished with workplace cyberbullying. With traditional bullying, the imbalance of power is associated with the perpetrator's physical and psychological power in the real world. However, with cyberbullying, it is not only limited to the features of the perpetrator, but the 'power of technology' and may be based on the lack of power of the target, rather than the power possessed by the perpetrator (Dooley, Pyzalski, & Cross, 2009). While the victim or target in traditional bullying has the power to leave the organization and end the bullying experience, with cyberbullying this may not be so. The feeling of helplessness can have far reaching implications on the psychological imbalance imposed on the victim. These features have led researchers to argue that cyberbullying has a stronger psychological impact than traditional bullying as there is the ongoing humiliation resulting from being abused online and the potential repercussions for the victim's career and reputation.

Fifthly, with cyberbullying the victim can use the *digital evidence* to report the bullying incidents and for the organizational agent to deal with the reported case. Using the phone caller identifiers, call records, text messages, emails, IP addresses, SIM cards, and website posts have been found to be useful as tangible proof for the target and employers. This available proof act as a shield for the victims and allow them to protect themselves (Cruz & Noronha, 2017). However, with cyberbullying, there is a higher probability that the bully would be more vigilant in concealing his/her identity. When the bully is anonymous then it is challenging for the victim to identify the bully. Further contributing to the under-reporting of cases, organizations are failing to develop and implement cyberbullying policies to

objectively address reported cases of this phenomenon. The lack of interventions to deter cyber abuse in the workplace is enabling such incidents to proliferate.

The Antecedents of Cyberbullying at Work

Communication through digital devices in the workplace is becoming more prevalent, further increasing the possibility for cyberbullying behaviour. Empirical evidence on the antecedents of workplace cyberbullying is relatively sparse. Consistent with research on cyberbullying among adolescents and traditional bullying, stressor evoked emotions of fear and sadness were found to predict exposure to workplace cyberbullying. Further, these mechanisms were significant explanatory reasonings for the relationship between work stressors and exposure to workplace cyberbullying (Vranjes, Baillien, Vandebosch, Erreygers, & De Witte, 2018). Therefore, workers who are sad and fearful are more vulnerable to being targeted by someone in the organization using cyberbullying tactics.

The Implications of Cyberbullying at Work

The technological advancements are expanding at an increasing rate with organizations trailing behind in their attempts to develop and implement codes of conduct to manage cyberbullying behaviours. Added to this is the paucity of research on the impact of cyberbullying in the workplace. While the impact of workplace cyberbullying is not widely studied and understood, extensive research has been conducted on the consequences of traditional bullying on the target/victim and organization.

When false allegations are made about an employee in a public platform, there is the ongoing humiliation and distress experienced. There is the potential for the victim's reputation and career to be adversely affected. Bullying has direct and indirect repercussions for an organization, its reputation, and the potential for negative publicity. When enacted on the internet, the implications for the firm is far-reaching as the scope of harm by a cyberbully can have an outward spiralling dynamic that transcends the internal organizational boundaries. When an employee is being targeted in public forums, reference can be made to the organization which is visible to potential customers, potential investors, and potential employees.

Health-Related Implications of Cyberbullying

Research has consistently shown that workers who are bullied are at a higher risk of negative psychological problems (for instance posttraumatic stress disorder), physical problems (for instance physical abuse, fatigue, muscular complications), physiological problems (for instance diminished self-esteem, emotional exhaustion, shameful feeling, and neuroticism), and psychosomatic problems (for instance sleeplessness and chronic depression). The health-related outcomes of cyberbullying have predominantly been explored from the adolescent's mental health perspective. Some of these effects include increased risk for mental health issues, depression, anxiety, stress, social difficulties, aggression, decreased self-esteem, delinquency, substance abuse, rule-breaking behaviour, and suicidality (Nixon 2014). The reactions to cyberbullying may depend on the form of cyberbullying experienced by the target where adolescents who were victimized via a computer (for instance email, online posts, graphics) experienced greater harm than adolescents victimized via a phone (for instance phone calls, text messaging) (Raskauskas & Stoltz, 2007). Based on the similarities in the health-related effects on targets of both traditional workplace bullying and cyberbullying among adolescents, workplace cyberbullying is expected to have severe implications on the health and well-being of the targeted employee.

Work-Related Implications of Cyberbullying

From the organization's perspective, productivity can be affected as the victims spend more time worrying about incidents when they occur and the likely future interactions with the perpetrator. Some studies have identified work-related implications of workplace cyberbullying. For instance, a study conducted by Lim and Teo (2009) found that female supervisors engaged in passive cyber incivility and male supervisors engaged in active forms of cyber incivility. Their findings also revealed that there was a negative relationship between cyber incivility and employees' job satisfaction and organizational commitment. Interestingly, employees who experienced cyber incivility engaged in deviant behaviour against their organization or were more likely to quit their jobs. In another study conducted by Coyne et al. (2017), the researchers found that those exposed to cyberbullying, when compared to traditional bullying, display a stronger negative relationship with job satisfaction. They concluded that cyberbullying may have more severe outcomes than traditional bullying due to the differences in the strength of the relationship. Muhonen et al. (2017) found that the relationship between cyberbullying behaviour and health, well-being, work engagement, and intention to quit can be mediated by the social organizational climate. Furthermore, there was a stronger indirect effect of cyberbullying behaviour to health, well-being, work engagement, and intention to quit than direct relationships. Stemming from the consistency in the findings, these studies suggest that victims experience lower job satisfaction and higher turnover intentions.

SOLUTIONS AND RECOMMENDATIONS

This new workplace hazard requires systematic efforts towards formulating awareness, prevention, and intervention strategies. The failure to systematically address cyberbullying activities can escalate where intra-relationships are disrupted and eventually evolve into a dysfunctional organization as victims may retaliate by engaging in deviant behaviours as well. There is the increasing need for cyberbullying interventions as proactive approaches should be given priority to effectively resolve such incidents. Organizations need to communicate that it takes cyberbullying seriously and such behaviours will not be tolerated. Specifically tailored interventions are necessary beyond those adopted for traditional bullying. Given the scope and permanence of workplace cyberbullying, the following recommendations are advanced to manage and address cyberbullying:

Internal policies: Organizations should develop a formal policy after consultation with stakeholder groups such as employees, and trade unions. Having a well-organized response can restore the confidence of employees when they recognize that grievances will be handled in due process. In developing an internal policy, the document should entail certain key aspects: a specific definition of cyberbullying; a list of the types of workplace cyberbullying (employees can label their experiences); a detailed grievance process (guidelines in making a formal complaint, the agent to investigate the complaint, the process of investigation, the report submitted upon completing the investigation). Redress mechanisms should be enforced, to be effective in curtailing workplace cyberbullying.

Communication: The cyberbullying policy should be communicated to all staff. A zero-tolerance approach should be communicated throughout the organization to deter cyberbullying behaviours where the bully is dealt with in an expeditious manner. The consequences for violations should be outlined and enforced. Formal statements should be issued to all employees on how the cyberbully was punished to enforce the zero-tolerance approach and to dispel rumours that may be circulating throughout the organizational grapevine.

Mediation between the parties involved: When an employer receives a complaint, it should be addressed in a prompt and thorough manner. In instance where the perceived cyberbully did not realise that the behaviour was unacceptable, the matter can be resolved through a meeting with the two parties that is facilitated by a designated organizational agent. The facilitator can determine if the matter should proceed to a formal complaint being made and disciplinary action taken or if the perpetrator recognises that the behaviour is unacceptable, apologizes, and is committed to changing their ways.

Counselling: The organization should offer professional counselling services to assist victims with the psychological trauma that they may experience. This should be coupled with stress management intervention and coping strategies that can be incorporated into their employee wellness programme.

Training: Sensitivity training on workplace cyberbullying and communicating through the internet should be conducted. Employees will have more information, gain knowledge, and establish a consensus regarding netiquette, acceptable behaviour in electronic communication and the tone of messages sent. Organizations should adopt a proactive approach and communicate with employees on how they can report instances of cyberbullying. This should include the appropriate use of ICT at work; maintain professional boundaries, and privacy settings. Additionally, self-help literature and educational material should be made available to all employees. This should contain approaches to deal with the emotional effects of workplace cyberbullying.

Bystanders: The role and importance of bystanders as key agents in workplace bullying intervention is gaining attention. With cyberbullying, bystanders would play a critical role in deterring bullying by training employees to detect and report incidents. By fostering a supportive organizational culture, witnesses would be willing to come forward to support the claims being made by co-workers. Therefore, organizations must ensure that there are transparent reporting procedures.

Awareness at a National Level: As countries around the world seek to empower their workers and protect them against workplace bullying, current national laws and legislation should be amended to include workplace cyberbullying. Further, to increase awareness and sensitise the public, communication media such as newspaper articles, radio/television programmes, and social media can be effective tools. Trade union involvement to disseminate information to its members can also be a medium to increase awareness of workers.

FUTURE RESEARCH DIRECTIONS

Workplace cyberbullying is an emerging issue that is proliferating at an alarming rate. In order to curtail its occurrence, there is the increasing need to deepen understanding of this phenomenon. Given the current debate on the conceptualization of workplace cyberbullying, further probing is necessary to consider the unique aspects for policy development and effective management. From a legal and organizational perspective, concise differentiations would allow the target to identify and determine the nature of the behaviours.

Future research should explore the implications of the direction, repetition, and form used by the cyberbully. The intensity of the psychological, physical, emotional, and physiological effects on the victim may be shaped by the tactics used by the cyberbully. Therefore, the effects may vary when the cyberbully engages in direct or indirect cyberbullying behaviours, the frequency of the acts, and the use of a computer or a cellular phone. Further, the relationship between cyberbullying, its causes and its consequences are difficult to differentiate. To address this causality dilemma, researchers should apply longitudinal research designs when exploring the antecedents and consequences.

CONCLUSION

In conclusion, workplace cyberbullying is not a trivial issue as it is even more complicated than traditional bullying. There is the critical need for continued research as this area is at its embryotic stage with many unexplored areas as the theoretical discourse regarding this phenomenon is limited. While this phenomenon is grouped as workplace aggression, understanding its unique features and the implications for workers, organizations, and society is necessary with the ICT revolution. As communication through digital devices and social media in the workplace proliferates, there is a danger that cyberbullying behaviour also might become more rampant. Practical interventions need to be developed and implemented to curtail workplace cyberbullying from becoming embedded into the cultures of organizations.

KEY TERMS AND DEFINITIONS

Cyberbully: A person who directly or indirectly uses technology to reduce another person to a psychologically inferior state.

Cyberstalking: A form of harassment where the cyberbully makes continuous threats and sends inappropriate messages to an individual in the form of text messages, instant messaging, social media, emails.

Digital Evidence: Information that is stored and transmitted on digital devices.

Information and Communication Technology (ICT): Telecommunication technologies that provide access to information such as the internet, wireless networks, cell phones, and other communication mediums.

Masquerading: The creation of an anonymous or fake identity by an individual to harass another individual.

Traditional Bullying: An escalating process in which one or more employees are subjected to negative psychological and physical abuse recurring over an extended period of time, where the target is reduced to a psychologically inferior state and it creates a hostile work environment to those exposed.

Workplace Cyberbullying: An escalating process in which an employee is subjected to perceived psychological abuse recurring over a period of time where the perpetrator uses some form of technology.

Cyber Crime Against Women and Girls on Social Sites in Bangladesh

Rajshahi University, Bangladesh

INTRODUCTION

The advent of the Internet and modern communication devices with multiple features like camera, radio, general packet radio service and Wi-Fi networks and the wide diffusion of social media have made dramatic changes in human lives. It has created a virtual world with no boundaries; allows people to develop both personal and professional relationships across borders. The World Wide Web (WWW) permits users to disseminate content in the form of text, images, video, and audio. Worldwide, the number of people using the Internet is increasing day by day (Mala, 2016; UN Broadband Commission for Digital Development, 2015). As of June 30, 2018, more than half of the total world population i.e. 4.2 billion (55.12%) is using the Internet (Internet World Stats, 2018) for entertainment, business, education, information sharing and other purposes. In addition, social networking websites (SNWs) like Facebook, MySpace, YouTube, Flickr, LinkedIn, Snap chat, Twitter have developed a new platform to meet people. Around 2.62 billion people use different social network sites (Statista, 2018). It allows people to share ideas, pictures, posts, activities, events, and interests with people in their network. Regardless of any distinction, women in society are enjoying this liberation. It allows them to share their experiences with the whole world; their success stories as well as their problems (Halder & Jaishankar, 2009).

However, social sites have also created avenues for various criminal activities. Cybercriminals abuse the technology to abuse people for financial gain, to take revenge, to defame, to ridicule and humiliate for their self-enjoyment and so on. Therefore, social sites put people at risk while it makes life easier, safer, and more social. Pew Research Center (2014) reports that 73% of the adult Internet users have witnessed someone be harassed online and 40% have personally experienced it. The Internet Crime Complaint Center, known as IC3 received 3,463,620 cybercrime complaints since its inception. According to the IC3 report, the total cybercrimes reported in the US shows a steady increase from 2013 to 2015. In 2013, the number of cybercrimes reported was 262,813; in 2014 it was 269,422 and in 2015 it further augmented to 288,012. The Office for National Statistics reported that there were 5.1 million estimated cybercrimes and scams in England and Wales in 2014 (Mala, 2016).

Women are more vulnerable to cyber threats than men are as the offenders were unaccountable for the offences they commit. Moreover, the criminals are committing traditional crimes using the latest information technology as committing the crime is easier and investigating it gets tougher. In the contemporary world, instances of cybercrimes against women are increasing alarmingly (Halder & Jaishankar, 2009). According to the United Nations Broadband Commission Report (2015), women aged 18 to 24 years are at risk of cybercrime victimization. EU estimates show that one in ten women has experienced some form of cyber violence since the age of 15 and the impact on their lives is far more traumatic (European Institute for Gender Equality, 2017). Women are receiving unwanted emails often containing indecent and obnoxious language. The vulnerability and security of women is a major concern globally (Halder

DOI: 10.4018/978-1-5225-9715-5.ch048

& Jaishankar, 2008). According to IC3 (2015), in the US, 47.09% of the cybercrime complaints were reported by women. Women made 70% of the cybercrime complaints to the Working to Halt Abuse, a non-profitable organization, from 2000 to 2014 from all around the world. The organization further stated that 42% of the victims did not report their victimization (Mala, 2016). Statista (2017) reports that worldwide 57% of the surveyed women experienced abuse or harassment via Facebook.

Like other parts of the world, the number of Internet users is growing very fast in Bangladesh specifically, through mobile networks. There are 85.92 million Internet subscribers as of April 2018 and among them, 29 million are registered Facebook users; one-third of the subscribers of the Internet are women (BTRC, as cited in Akter, 2018). The average time people stay on Facebook and other social sites has gone up in recent times. People consciously or unconsciously reveal too much of their personal life. Bangladesh ICT Division's Cyber-Help Desk received more than 17,000 complaints; women made 70%. It is found that more than 60% of women faced some form of harassment on Facebook; about 10% of them filed complaints that their images were stolen, merged with pornographic images, and made available on the Internet (Rabbi, 2017). However, they mostly avoid legal assistance due to social stigma.

The Cyber Crime Awareness Foundation Bangladesh (CCABD) reports that 51.13% of women are victims of cybercrime. Women belonging to age group 18 to 30 years mostly become the victim of such crimes (73.71%), while 0.52% are below the age of 18, and 12.77% are of 30 to 45 years and 3% are above 45 years of age. Women Facebook users are often victims of fake accounts and hacking. Once a fake account is created, the stalker spreads propaganda through the accounts; study reveals that 9.77% of women are the victims of such stalking. In addition, the offender can easily send threatening messages to the victim and harass her ("51.13pc women harassed on social media," 2018). However, identifying criminal is a difficult job due to the lack of evidence and fear of defamation.

OBJECTIVES

The objectives of this study are:

- To understand the impacts of cybercrime on women in Bangladesh;
- To find out existing schemes and mechanisms to deal with the offenders of cybercrime; and
- To explore remedial measures to protect women and girls against cybercrime.

LITERATURE REVIEW

Research on cybercrime against women and its consequences is an emerging field. There have been a number of studies on cybercrime against women in the international arena.

Sankhwar and Chaturvedi (2018) recognized cybercrime as a major challenge facing law enforcement agencies in India. They claimed that digital space in India opened doors to cybercriminals and the offenders used the cyber platforms to harass and abuse women and children. They focused on the existing legislative intervention measures and prescribed a few suggestions to curtail cyber-crime against woman and children.

Uma (2017) explored common forms of cybercrimes committed against women in India. She claimed that the existing provisions regarding information technology failed to realize women's experiences. The study recommended amendments in the laws to ensure remedies for the female victims of cybercrime.

Singh (2015) discussed the reasons for and forms of cybercrime against women in India. The study further focused on the impact of cyber violence on their social life and gave some suggestions to curb cybercrime against women.

Winkelman, Early, Walker, Chu, and Yick-Flanagan. (2015) examined women's experiences with and attitudes toward cyber harassment on social media in the USA. The study found around 20% of the participants received a sexually obscene message on the Internet. Moreover, more than 10% of repetitively received pornographic messages from strangers. Among the victims, more than a third reported feeling anxious and one-fifth noticed changes in their sleeping and eating patterns as well as feeling helpless due to the harassment.

Gitonga (2014) studied the effect of Internet crimes on women students at the University of Nairobi. The researcher claimed that female victims of cyber oppression and attacks may fail to utilize the benefits of the Internet. Conversely, they might stop using the Internet to protect themselves. Therefore, the Internet worked as a double-edged sword because it empowers and put users at risks.

Sissing (2013) in a study on cyberstalking in South Africa found that women belonging to the age group of 18 to 25 years were the main victim of cybercrime. They further claimed that the female victims were cyberstalked through social networking sites by outsiders.

Halder and Jaishankar (2011) conducted a comparative study to examine the criminal justice systems regarding protection of women harassed online in countries like the United States, the UK, and India. They claimed that the judicial interpretations of the term "gender harassment" have caused secondary victimization of women as many of the cybercrime activities have not been legally interpreted as "gender harassment" in the laws. As a result, the police are often not interested to investigate properly, and the trial may fail to help the victim due to a lack of relevant laws that make the female victims suffer.

However, scholarships on cybercrime against women in Bangladesh are scanty. For instance, Kabir (2018) discussed the extent and types of online/cyber violence and harassment against women and girls and its impact on their daily lives. She further shed lights on the existing laws and regulations to combat cybercrime in Bangladesh.

Ahmed, Kabir, Sneha, and Jafrin (2017) focused on female Facebook users in Bangladesh. They also identified the threats and risks associated with the disclosure of their personal information on Facebook. This paper also suggested some remedial measures to facilitate their rights to online privacy.

Cybercrime against women is at an alarming state in Bangladesh; it has caused the most traumatic experience for women. There is a need to inform about the pervasiveness and different forms of cybercrimes taking place against women and girls and to make them aware about the safety precaution when utilizing the Internet as well as the existing remedial measures. This study is expected to fill the research gap, as a few scholarships on cybercrime against women using social sites in Bangladesh are available.

METHODOLOGY

This study followed a qualitative case study method to understand the nature and types of cybercrime committed via Facebook and Messenger against women as well as the effect of cybercrime on their lives. The participants were approached by sending private messages on Facebook Messenger and 35 agreed to participate. However, participants were selected only if she was a victim of cybercrime on Facebook and/or Messenger. Finally, 12 were selected for semi-structured online interviews. The interview questions were designed to collect background information like age, education, and occupation of the participants as well as to collect information on their experience of harassment on Facebook and Messenger and their

opinions on how their rights can be protected on social sites. Participants were asked whether they used safety tips like locking personal albums, information, and personal walls of social networking sites, or shared emotions/feelings with virtual friends whom they did not meet in real life. In addition, Secondary data were collected from books, journals, reports, newspapers, documents, and the Internet.

Responses to questions obtained from each participant were coded in the same category. Then data was coded into analytical units. Raw data were organized in order to develop findings, conclusions and recommendations manually. Results were presented through narrative text, simple computations, and analytical reasoning.

CYBERCRIME

Cybercrime is a universal problem now. The first cybercrimes took place in India, Japan and China in 1820. Gradually, extent, type and nature of cybercrime increased and by mid of 20th century, it became a serious issue globally. Around the world and in the Middle East and third world countries the expansion of Internet connectivity in recent years has led to the increase in cybercriminal activities (El-Guindy, as cited in Kamal, Chowdhury, Haque, Chowdhury, & Islam, 2012). There is no specific or universal definition of cybercrime as different agencies and researchers define the concept based on their context. It is also known as “computer crime,” “computer-related crime,” “high-tech crime,” or “Internet crime” (Brenner & Goodman, as cited in Kamal et al., 2012). A new dimension of cybercrime is adding almost every day.

Wall (2005; 2008/11) asserts that cybercrime refers to insecurity in cyberspace. The term generally refers to any harmful activity that is in some way related to the misuse of computers, more recently suggesting to networked computers. The Council of Europe (2001) suggests the following acts as cybercrime:

- Offences against the privacy, integrity and obtainability of computer data and systems;
- Traditional computer-related crimes;
- Content related offences;
- Breach of copyright and crimes to related rights; and
- Crimes involving the violation of privacy.

The Lawyers and Jurists Bangladesh (2017) defines cybercrime as a criminal activity that may range from illegitimate access through the computer; transmissions of computer data to, from or within a computer system illegally; unauthorized damaging, deletion, deterioration, alteration or suppression of computer data; misuse of devices; forgery/theft, and electronic fraud. This includes anything from downloading illegal music files to stealing millions of dollars from online bank accounts or inventing and spreading viruses on other computers or publishing secret information on the Internet. Therefore, cybercrime is an offence committed with a criminal motive using modern telecommunication networks like the Internet. Cybercrimes can take place against an individual, against the organization, against the economy, against society or against the state (Hanif, 2016).

COMMON FORMS OF CYBERCRIME AGAINST WOMEN ON SOCIAL SITES

Women especially young girls with little or no experience about the cyber world are an easy victim of cyber criminals who may be either male or female. The extent of victimization depends on a number

of factors, like, the sexuality of the victim, her ideologies, marital status, profession, the regularity of her partaking in selected groups, the language she uses, her popularity in the groups and so on. Male offenders mostly attack the victim for sexual purposes like morphing, using the image for pornographic purposes, cyberstalking etc. and non-sexual purposes such as harassment and bullying. However, female criminals attack the victim mostly due to ideological differences, hatred or taking revenge (Halder & Karuppannan, 2009). The offences against women and girls occur in the social sites are:

Cyber Verbal Abuse by Groups of Perpetrators Spreading Hate: A female member of the social site may be attacked by a group of criminals both in the community wall and also in her own message board (Halder & Jaishankar, 2008).

Cyber Defamation Targeting the Individual: The male member spread lies about the female member to other members through his own posts, community walls etc. after emotional breakups (Citron, 2009; Halder & Jaishankar, 2008).

Cyberstalking: Women and children are the most likely targets of cyberstalking. Here the offender uses the Internet to stalk someone for online harassment and abuse. A cyberstalker follows the victim's online activity, collects information, and makes threats and intimidates verbally (Halder & Karuppannan, 2009; Sankhwar & Chaturvedi, 2018).

Morphing: The criminals download an original picture of the victim from social media, or some other sources, edit and upload morphed photos on social media sites or porn sites for pornographic purposes (ibid).

Cloning: Cloned or fake profiles of female victims are created using her personal information. The cloned profile makes people confused. The cloned profile sends add requests to the victim's friends and crack their privacy for evil purposes. This is very common in social sites like Facebook, Myspace and Orkut (Halder, 2007).

Cyber Obscenity: The victim's photograph is used, morphed and distributed on the Internet with indecent postures. The attacker may also post obscene messages on her wall (Citron, 2009).

Hacking: Personal information of the victim is used for evil purposes. Targets are chosen and their profiles are hacked for sexual purposes. The harasser may even distribute open invitations for having sex with the profile owner at her home address (Citron, 2009; Halder, 2007; Halder & Jaishankar, 2008).

Cyberharassment: It may take the form of continuous messaging to the profile's wall or personal e-mail address, regular spying and messaging in her wall, constantly sending friend requests, become a member of groups where she is a member etc. (Citron, 2009; Halder, 2007).

Virtual Rape: Virtual rape is a violent type of cyber victimization where the targeted woman is taken up by a harasser with messages like "I will rape you," or particular group members may attack together with slang and dirty words that lead other members to comment on the victim's sexuality. The profile owner becomes a hot topic for erotic conversations or addressing by vulgar name etc. (Citron, 2009).

Cyberbullying: The offender may continually bully the target in the social sites where either he or she is a member. Women are the most likely targets for their sexuality, emotional breakup or even domestic violence by their ex-spouse or ex-lover (Citron, 2009; Halder & Jaishankar, 2008).

Impersonation and Cheating: Social sites allow for creating multiple ids under pseudo names, hiding one's real age, sex and other information. This gives the culprits the opportunity to flirt with women members (Halder & Jaishankar, 2008). The harasser convinces the victim in such a way that she is encouraged to share her secrets, and even have erotic chats with the criminal. When the victim puts pressure to meet the offender physically, he blackmails the victim or cheats the victim (Halder & Jaishankar, 2009).

IMPACTS OF CYBER CRIME ON WOMEN IN BANGLADESH

West (2014) conducted research on cyber violence against women in the US. She found several psychological, social, physical, and economic impacts of cyber violence on women. The most dominant emotional impact on women ranges from anxiety to thoughts of suicide and engaging in self-harming behavior. Cybercrime, particularly nonconsensual distribution of images and revenge porn against women might have serious and detrimental economic effects on women. Women might lose their jobs because of their nude picture circulated on the Internet. Revenge porn images and defamation may create lifetime troubles for women and make it difficult to get new jobs or progressing in their present job. Cybercrime can exacerbate or lead to physical violence against women. If the offender is refused, he may attack the victim physically. The social impacts for women can be very severe. They might feel isolated from friends and family. Her friends and family may turn against her. Therefore, often women act in accordance with their abuser's threats to avoid such repercussions. Furthermore, the victim withdraws herself from online activities.

The situation is similar in Bangladesh. Women and young girls who use digital platforms experience some form of cybercrime over their lifetime. However, morphing, cyberstalking and cyber pornography including revenge porn are the most common cybercrimes committed against women to destroy their personal reputation, create fear and monetary losses. Bangladesh is a country where gender-based harassment committed in public spaces, homes and workplaces go unpunished. Therefore, victims of cyber sexual harassment and/or cyberbullying barely report in public or complaint to the police (Preetha, 2015; Supan, 2015).

Bangladesh is a conservative society where the effects of cybercrime not only affect women victims; it has a chain reaction on their families. Majority people have a tendency to believe everything posted on social media due to lack of awareness, ignorance, and education. They enjoy such content and like to spread gossip that intensifies the victim's suffering by a thousand times. The victim's family members also face social exclusion, humiliation and public resentment (Karaman, as cited in Akter, 2018). Such criminal act may lead to depression, guilt, humiliation, and fear of harm to self and family members and destroy the victim's career, education, and social life. Some victims take the route of drug addiction while some commit suicide. Only a few of the victims recover from such a tragedy. From 2010 to 2014, Bangladesh National Woman Lawyers' Association identified 65 suicide attempts by female victims due to cybercrime. In addition, every year, on average, 11 suicide attempts by women take place because of cyber violence (BNWLA, as cited in Akter, 2018). A few examples of cybercrimes committed against the participants:

Case 1

Ms X is a third-year university student using Facebook for the last five years. She had no idea of cyber-crime on social sites and accepted friend requests from all. She made a special Facebook friend who claimed himself a final year medical student in another city. Their online relation was so close. One day the boy asked for some explicit pictures of her. She gave him the photos. Afterwards, they met in person twice. Subsequently, he demanded to have physical sex that she refused. The man then began to send her nude images and adult videos with derogatory comments about her appearance and character. She blocked him. He then blackmailed her and threatened to inform her parents and relatives. She felt helpless and afraid of sharing this incident with her family. Because of fear, she was compelled to fulfil his

demand. She does not want to make any complaint formally due to afraid of spreading the news among her family members and still under the grip of that man.

Case 2

Ms Y is a Master degree student at a University. She met a boy on Facebook which turned into a love affair. She spent some private moments with him at a hotel room for three to four times. Suddenly, the boy started blackmailing her for money threatening to spread private moment's videos of her on the Internet which was captured with a hidden camera. She informed her family members. Fortunately, her family was very supportive and they filed a case to the police.

Case 3

A year 12 student was a member of Facebook. Her cousin who once proposed her and was refused by her used Facebook to humiliate her. He spread messages on Facebook that the victim was responsible for shattering his life. Relatives and friends of the perpetrator trusted the gossip and started molesting and abusing the victim. She was sleepless for several nights; had an eating disorder; felt helpless and isolated as her friends and family members started avoiding her. She lost her concentration on studies. She was so frustrated that tried to commit suicide. At last, her family took her to a psychiatrist for treatment.

Case 4

A working woman suffered as her Facebook accounts were hacked several times. The offender was ex-husband of her. They both were members of a similar Facebook group. The perpetrator started following her after their divorce. He stalked the victim regularly and contacted her friends to harass her. She was so upset that failed to concentrate on her job for several weeks. She could not communicate with her colleagues at the office. The incident affected her professional career. Hre ex-husband took help from a hacker to hack her account. The hacker hacked her account, posted unpleasant pictures on her wall, and tried to blackmail her. The woman felt panicked and made a complaint to the police.

The magnitude of such incidents is increasing day by day in Bangladesh. Ahmed et al. (2015) conducted a study on cybercrimes against women. The study found 36.8% users had been harassed, and 78.9% faced unusual situations, which can be treated as harassment. 84.2% of users had been harassed by the people with whom they are connected at Facebook. Most of the harassment around 27% is coming from the unknown people met at the Facebook first time. The study also found 10.5% harassment from completely unknown and 5.3% from a known person. The interview data revealed that as the female users are less concerned about the privacy settings of Facebook, their profile and personal information or photos were accessible by every registered Facebook users and they remained the easy target of the cybercriminals.

It is a common practice among young girls of making friendship with a stranger on Facebook and share personal feelings with him. At first, the girl fails to realize the consequence of entering into a relationship with a stranger. The problem arises when the so-called Facebook friend starts to exploit her emotions and feelings. In most of the time, the victim feel helpless and frustrated, has no idea about what to do or where to seek help. As the victim feels that reporting the incidents would lead her to face intrusive questions about her character and bring disgrace to her and her family rather than justice, she does not seek legal remedies (Kabir, 2018; Preethi, 2015). Similar findings were revealed during interview ses-

sions with the participants. Most of them did not want to complain or inform their family due to fear of humiliation. Moreover, women who try to report or file cases have to experience further victimization and harassment. Deep-rooted patriarchal attitudes of the institutions rather make the situation worse for women. For example, if a woman visits the police with complaints that her explicit pictures are being spread on the net, the police (may) seem more interested to listen about her relationship in detail and staring at the pictures than helping her. In this situation, even if a woman is courageous enough to report the crime, it does not guarantee justice finally. Furthermore, law enforcement agencies often do not have the technical expertise or intention to address cases of cyber sexual harassment as it is often difficult to track or identify the perpetrators because of fake profiles and addresses (Preethi, 2015).

LEGAL PROCEDURES AND MEASURES TO COMBAT CYBERCRIME IN BANGLADESH

There is a lack of universally recognized law, convention, or rules to deal with cybercrime taking place in the social sites. Moreover, the majority of the social site users are registered under the US laws section 230 of the Communication Decency Act, 1996 that protects them from being charged as an offensive media. However, this creates a problem for victims, especially women. In addition, the meaning of obscenity varies across societies. The US has the Violence Against Women and Department of Justice Reauthorization Act of 2005 to protect women from cyber-harassment or cyberstalking. In contrast, the UK does not have any specific law to protect cyber offences against women. However, there are several laws like the Computer Misuse Act 1990, Police and Justice Act 2006, Sexual Offences Act 2003, The Prevention of Sexual Offences (Scotland) Act 2005, Protection from Harassment Act 1997, Malicious Communications Act 1988 to prevent cybercrime against women. Nevertheless, cyber offences are not legally defined that allows criminals to escape punishment very often. Canada controls the online victimization of women through specific chapters of Canadian Criminal code applicable for both gender and there are no special laws to protect women. Indian law does not recognize many of the offences that occur online like cyberbullying, cyber eve teasing, cyber-harassment, cloning of the profile etc (Halder & Jaishankar, 2009; 2011).

The Government of Bangladesh (GOB) has adopted several initiatives and laws to control and prevent cybercrime. The Constitution of Bangladesh ensures equality before the law to all its citizens irrespective of sex and prohibits all types of discrimination. However, there is no comprehensive law or section adequately dealing with sexual harassment in social media and other digital platforms.

Section 500, 504 and 509 of the Bangladesh Penal Code, 1860 imposes a penalty for defaming any person. However, the Penal Code is more than 150 years old and not effective to deal with online harassment today. The Nari O Shishu Nirjatan Daman Ain (Suppression of Violence against Women and Child Act), 2000 penalizes 'sexual oppression' including any indecent gesture and the disclosure of the identity of a victim in the media as an offence.

According to section 69 of the Bangladesh Telecommunication Control Act, 2001 sending any obscene or indecent message is a punishable offence. Nevertheless, the 'Telecommunication Act 2001' does not address the gender-based violence that takes place on the Internet (Kabir, 2018).

Section 57 of the Information Communication Technology Act 2006 (amended 2013) has provision for penalty of maximum 10 million BDT as fine and a maximum jail sentence of 14 years and minimum seven years imprisonment if someone (male/female) publishes fake, obscene or defamatory information in electronic form that causes to deteriorate law and order, prejudice the image of the State or person or

causes to hurt religious belief. It also states that the crime is non-bailable. However, the Act does not define gender-based violence online or not define what constitutes “obscene” that helps the criminals to escape punishment (Ahmed et al., 2017; Akter, 2018; Kabir, 2018).

The Pornography Control Act, 2012 states that if any person produces or agrees to supply participants to make pornography, or forces any person to take part in the production of pornography, he/she will be punished for a maximum of five years imprisonment and a fine of 2,00,000 BDT. Moreover, the production of pornography is also punishable by a maximum of seven years sentence and a fine of 2,00,000 BDT. Furthermore, this is a non-bailable offence. However, the Pornography Control Act fails to properly control and combat the heinous crime due to institutional corruption and powerful allies of the criminals with the ruling party. The offender remains safe if he has power and the victims are poor (Akter, 2018; Kabir, 2018).

The GOB has established a fast-track court (2013) to deal with cybercriminals and complete trials within six months. In addition, GOB has formed a ‘Cybercrime Tribunal’ to address cyber violence. However, 90% of victims do not complain to the Tribunal. The Right to Information (RTI) Act states that from 28 July 2013 to 10 February 2016, the Cybercrime Tribunal received 520 cases of which 328 cases were dropped (Ahmed et al., 2017; Akter, 2018). Furthermore, Bangladesh police have opened a cyber-wing to deal with cyber threats. The wing also monitors cybercrimes and tracks the criminals. Additionally, Bangladesh Telecommunication Regulatory Commission (BTRC) is working to regulate and monitor cybercrime. This commission blocks inappropriate websites, blogs, and Facebook accounts if necessary (Akter, 2018).

The draft Digital Security Bill, 2016 later amended in 2018 has been presented in the parliament (Parliament Correspondent, 2018). It is expected that the act will assist to combat cybercrime in Bangladesh. This act empowers the GOB to establish National Digital Security Agency (NDSA) headed by a Director-General to monitor, observe and take necessary steps in respect of all the Bangladeshi computers or digital systems, networks, mobiles or digital communication (voice and data) networks to secure, prevent and curb cybercriminal activities in Bangladesh. In addition, NDSA is allowed to establish a digital forensic lab for cyber forensic analysis and Bangladesh Cyber Emergency Response Team (Bangladesh-CERT) for an instant response against cybercrimes. Besides, The Act has the provision of establishing a National Digital Security Council (NDSC) chaired by the Prime Minister to discuss cyber-related issues and take immediate decisions. All the offences committed under this act are triable in the cyber tribunal and cyber appellate tribunal established under the ICT Act, 2006 (Hanif, 2016).

RECOMMENDATIONS

In Bangladesh, the lawmakers and enforcers are interested to satisfy the ruling elites. Therefore, it is seen that the digital act is more concerned about the denigration of the prime minister and the president rather than protecting the women. Bangladesh government has adopted several cyber laws but the laws are not implemented properly. It is mostly seen that the victims feel hesitated to ask for legal assistance due to various reasons, especially for social humiliation. As these cyber laws have many loopholes, the offenders repeat the crimes repeatedly. In addition, the criminals get themselves free by giving bribes to the law agencies or through threats. Therefore, the existing acts need to be revised incorporating provisions for offences like cyber harassment; cyberstalking; violation of privacy; online trafficking and so on. Furthermore, there is a need to ensure strict penalties for cyber offences in order to discourage such offences in the future.

The GOB needs to revise the applicable regulatory framework through consultation along with the Bangladesh Telecommunication Regulatory Commission, which is more powerful to control any website, explicit contents or online based websites. Moreover, GOB may develop a broad framework with mobile service providers and Internet providers. Furthermore, Internet Service Providers and mobile companies providing or hosting social media services must be made accountable. They have to report criminal activities committed through their services; take away any criminal or offensive content, disclose the identities of such perpetrators. The identity of the complainants in both civil and criminal proceedings brought by women must be maintained strictly.

Digital Literacy and awareness campaign at the root level is must to prevent cybercrime against women and girls. Seminars and symposiums on cybercrimes, online privacy, possibilities and limits of the Internet and social sites, how to deal with such incidents, legal remedies need to be arranged regularly with women activists, teachers, responsible authorities, parents and young girls and boys. Open discussion between the government and the academics, civil society, youth-led organizations, legal aid based organizations, cybercrime specialists, and law enforcement agency is a must to deal with the problem.

The complex nature of cybercrime makes the investigation difficult for the law enforcing agencies as they are not well trained and equipped. The Police force and investigating agencies must be trained to tackle and handle cybercrimes. A guideline on how to use cybercrime related law may be developed. A Digital Police Portal or E-Portal may be established where victims can report their problems online.

Women groups and civil society should advocate for relevant legal and policy reform. In addition, they need to strengthen their existing networks and collaboration with government institutions. They may introduce awareness-raising program and training on cybersecurity.

School curriculum must be designed in such a way so that it covers all aspects of cybercrimes. Girls should be educated especially all types of cybercrimes and how to handle them. Media campaign on awareness building regarding uses of the Internet and security is essential. The attitude of the society towards women needs to change so that the victim woman do not feel isolated or helpless. Internet users need to be educated on privacy policy and their rights online.

The lack of universal laws to regulate social networking websites and the lack of legal recognition of the offences committed against women online has instigated the growth of cyber victimization of women (Halder & Jaishankar, 2009). Therefore, developing global cooperation is essential to deal with cases, as cybercrimes have no boundaries.

CONCLUSION

The growth of cybercrime on social sites in Bangladesh is on the rise. People use social sites for communication, information sharing, education, business and other purposes. However, it brings privacy threats due to some dishonest people. The problem is not using the technology rather using it unconsciously that affects women users largely. Due to the conservative culture, women still are not ready to report cybercrime immediately. Patriarchal norms and values are practised by men to establish control over women by committing crimes on social sites. As there are loopholes in the laws, the criminals commit the crimes frequently. The law enforcing agencies must deal with the cases on an emergency basis to create an example. There is a need for constant evaluation of cyber laws and procedure because women face difficulties while seeking justice due to lack of awareness. The GOB, civil society groups, NGOs, and women organizations need to work in collaboration to curb and control cybercrime.

FUTURE RESEARCH

The study only focuses on social sites specifically on Facebook and Messenger. Further study may be conducted on the ICT Act of Bangladesh and its' impact on women. In addition, a comparative discussion on the effect of cybercrime on urban and rural societies in Bangladesh may be an interesting research topic. Moreover, research may be designed to explore the status and nature of female cybercriminals in Bangladesh. Further research can be designed for investigating other social networking sites.

ANNEXE

The researcher arranged semi-structured interviews on Facebook Messenger with 12 female Facebook users. While they were asked, “are you a victim of cybercrime?” All of the participants admitted to being victims of cybercrime via Facebook. In majority cases, the offenders were an online friend whom they did not know before.

The question was asked, “do you know about Facebook privacy rules?” Nine of them said of being aware of the privacy settings. However, they did not maintain privacy and kept their profiles ‘public.’

Participants were asked to share their mental, social, and physical state after being harassed or abused online. They felt isolated and afraid of spreading the news among their family and friends. Therefore, they initially did not disclose the incidents. Later on, a few of them shared it with their close friends or family members and only two of them sought legal help.

While asking “do you know where and how to complain”? Surprisingly, 11 said of not being fully aware of the complaining procedure. However, seven of the victims said that they heard about it when one of their friend or family members informs them.

Participants were asked whether they know about the legal measures and laws relating to cybercrime in Bangladesh. Unfortunately, all were unaware of any cybercrime related laws. The GOB has launched 24 hours of national helpline for women and children. The hot number is 109. In addition, there is another police Emergency service 999. None of the participants was familiar with the services.

Regarding the punishment of the criminals, all of them said for an exemplary one like life- imprisonment so that the offender would never repeat the heinous act again. In addition, they said for attitude changes in the society towards women and new laws to combat digital crime.

KEY TERMS AND DEFINITIONS

3

Crime: Any illegal action that is considered an offence and is punishable by law.

Cyber: It refers to the features or characteristics of the culture of computers, information technology, and computer-generated reality.

Cybercrime: A crime that involves a computer and a network.

Internet: The Internet is an interactive medium based on a decentralized network of computers. The Internet may also be used to engage in other activities such as sending and receiving emails, money, trading files, exchanging instant messages, chatting online, streaming audio and video, every type of business purpose, and making voice calls.

Internet Crime Complaint Center (IC3): It was established to provide people with a reliable and convenient reporting mechanism to submit information to the Federal Bureau of Investigation (FBI) regarding cybercriminal activities and to develop cooperation with law enforcement agencies.

Social Networking Site: A social site is an online platform where people build social networks or relations with other people who usually share similar interests. A social networking service is a platform that increases group interaction and shared spaces for collaboration, social relations, and aggregates information exchanges in a web-based environment (Barlett-Brag, 2006).

Wi-Fi: A popular networking technology that uses radio waves to provide wireless high-speed Internet and network connection.

World Wide Web: The world wide web (WWW) is a network of online content on the Internet that allows documents to be connected to other documents by a link and enable the user to search for information by browsing on the net.

Nathan John Rodriguez

Weber State University, USA

INTRODUCTION

Technological innovations have fundamentally altered communication patterns during the past three decades. Smartphones have become widely adopted in recent years, and offer the allure of convenient access to news content, entertainment, retailers, weather information, and other people. In a practical sense, users sacrifice information regarding their online activity in exchange for content that is deemed relevant to their interests. There have been slightly different iterations of the axiom, “If the service is free, you are the product” over the past few decades, as it has come to signify the dangers of popular online platforms collecting consumer data (Oremus, 2018).

This entry examines internet privacy through four complementary, overlapping perspectives. It is argued that the most significant threats to internet privacy come through user activity, corporate data collection, governmental surveillance, and malevolent actors. To be sure, these are not discrete categories, but are frequently interrelated. For example, consumers frequently submit private information to corporate entities in exchange for access to online content. Before delving into further explanations and examples of these perspectives, it is necessary to begin with a discussion of what is meant by the notion of privacy and internet privacy.

BACKGROUND

Privacy Theories

One of the earliest definitions of privacy is “the right to be let alone” (Warren & Brandeis, 1890). The notion of privacy encompasses territorial privacy, personal privacy and informational privacy (Rosenberg, 1992). There are a variety of potential dimensions to informational privacy, but a broader definition of these concerns has been characterized as the unauthorized use of personal information. (Smith, Milberg, & Burke, 1996).

Online privacy studies have focused on the motivation for privacy protection as well as the behavior related to privacy protection. Internet privacy research frequently relies upon protection motivation theory (PMT), which posits that individuals engage in a rational thought process, and protect themselves based on the perceived severity of a negative outcome, the probability of that event occurring, and the efficacy of a potential solution (Rogers, 1975). PMT has undergone several iterations in recent years, and an extended parallel process model (EPPM) emerged to address these deficiencies by explaining why—even in the face of a high-perceived threat—a user may not change their behavior. Recent studies have shown that internet users “tend to ignore privacy risks until they encounter monetary loss online in person” (Chen, Beaudoin, & Hong, 2017, p. 300).

DOI: 10.4018/978-1-5225-9715-5.ch049

The Privacy Paradox describes the incongruent way in which users frequently express a theoretical interest in protecting their privacy, yet do not engage in behaviors that would protect their privacy (Norberg, Horne, & Horne, 2007; Brown, 2001). A thorough review of Privacy Paradox literature concluded that decision-making regarding privacy may be a rational calculation of risk and reward, a biased and irrational risk assessment, or a situation that involves virtually no calculation (Barth & de Jong, 2017). The authors concluded that decision-making tends to occur more frequently on an irrational rather than a rational level, as individuals tend to follow their intuition with little regard to privacy risks.

Attitudes Regarding Online Privacy

Sharing personal information online has become routine and more embedded in everyday social interactions (Zafeiropoulou, Millard, Webber & O'Hara, 2013). Privacy concerns were perhaps more prominent in the early days of the internet, but a rising percentage of people today are less concerned about potential risks due to "a growing internet population, constantly changing areas of use, and increasing security awareness" compared to earlier in the 21st century (Bergstrom, 2015, p. 425). Some internet users are fully aware of the risks they face online, and willingly accept those risks for access to certain services, thus engaging in a cost-benefit analysis (Park, Campbell, & Kwak, 2012; Preibusch, 2013). Consumers have been shown to willingly forego certain online privacy protections to access more customized content (Martin & Murphy, 2017; Sundar, Kang, Wu, Go & Zhang, 2013). It is quite possible that many users experience what Choi, Park, and Jung refer to as "privacy fatigue," an umbrella term for concepts ranging from security fatigue (Furnell & Thompson, 2009), to consent fatigue (Schermer, Custers, & van der Hof, 2014), and breach fatigue (Kwon & Johnson, 2015), in which users experience a "psychological state of tiredness with the issue of online privacy" (2018, p. 43).

It has been shown that people with a more sophisticated apprehension of the internet, who are better able to perceive privacy threats, are no better off than laypersons with respect to acting to secure their privacy online (Kang, Dabbish, Fruchter, & Kiesler, 2015). An over-reliance upon self-reporting studies could account for part of the discrepancy as there is a demonstrated tendency for internet users to be overly confident in their own competence. Jensen, Potts, and Jensen (2005) asked participants if they were familiar with technological solutions to enhance their privacy, and less than 25 percent of participants who answered in the affirmative were able to answer basic follow-up questions about the technology.

Concerns related to online privacy develop from personal experience, and include discussions with friends and family and hearing reports about data breaches through media channels that resulted in financial losses (Brandimarte et al., 2013, Bryce and Fraser, 2014). Simply put, many people may have become inured to the notion of their personal data being exposed online, and may appreciate those risks only after a negative experience. In 2016, there were more than 4,000 data breaches that affected more than 4.2 billion records (Risk-Based Security, 2017). These data breaches, in turn, often result in user information being sold on the dark web (Ablon, Libicki & Golay, 2014).

In the past few years, consumers have become more knowledgeable about the ways in which their data is being used (Morey, Forbath & Schoop, 2015). It has been argued that 2018 is the year in which consumers grew more informed and cynical about the ways in which their personal data is used (Ng, 2018), as a recent poll indicates a majority of Americans reported changing their privacy settings in the past 12 months (Perrin, 2018).

THREATS TO ONLINE PRIVACY

The article examines internet privacy through four complementary and overlapping perspectives: user activity, corporate data collection, governmental surveillance, and malevolent actors. To be sure, user activity is the most important factor, as a more established and connected online presence generally makes one more susceptible to having private information accessed without their consent or knowledge. At the same time, data collection by governments and corporate entities, as well as the activities of malevolent actors pose significant threats to user privacy. The primary focus is on the United States, as an endeavor to include other nation-states would inevitably exclude some populations while also sacrificing a more in-depth discussion of privacy.

User Activity

Certain individuals increase their vulnerability to being a victim of an online scam. A recent survey of more than 11,000 internet users demonstrated that weak self-control—by way of willingness to engage in risky investments—in addition to relatively mundane internet tasks, i.e. online shopping and opening emails from unknown sources, were factors that increased the likelihood of falling victim to online schemes (Chen et al., 2017). Aside from those relatively risky behaviors, more routine online actions can pose threats to a user's information privacy. The remainder of this section examines apps, Facebook, and the Internet of Things.

Apps

In 2019, smartphones are expected to eclipse TV as the popular medium, with adult users spending more than 215 minutes each day on their mobile devices—and 90% of that time on apps (Wurmser, 2018).

There had been a variety of anecdotal reports regarding the amount of data that apps collected on users. Personal injury law firms have sent advertisements to the phones of patients—and others—sitting in emergency rooms (Allyn, 2018). The CEO of Moviepass recently noted, “We watch how you drive from home to the movies. We watch where you go afterwards” (Fussell, 2018, n.p.).

An investigative report by *The New York Times* revealed that apps gathered a user's location information “as often as every two seconds,” and that more than 75 companies receive granular location data—often from local news and weather apps—with location accuracy within a few yards, and coordinates that are “in some cases updated more than 14,000 times a day” (Valentino-DeVries, Singer, Keller & Krolik, 2018).

Facebook

Facebook is the most popular social media platform in the U.S., with more than two-thirds of Americans having an account, and 75 percent of those users accessing the platform daily (Smith & Anderson, 2018). The more an individual uses various social media platforms, “the more overlapping, cross-referenced data” points are provided, since larger platforms buy or develop emerging platforms, “like how Facebook bought Instagram and WhatsApp, so they all connect data sets” (McKew, 2018, n.p.) This is potentially at odds with the expectation by consumers that popular platforms, e.g., Facebook and Twitter, should be the most adept at protecting sensitive information (Luttrell, 2019).

Advertisers have moved beyond using Cookies to using digital fingerprints from browsers, with some companies examining punctuation and tone in emails to establish personality profiles, while Facebook

has developed more than 50,000 attributes by which to categorize its users (Angwin, Mattu, & Parris, 2016). As Zeynep Tufekci (2018) put it: “What Facebook does is profile you. If you’re on Facebook, it’s collecting everything you do. If you’re off Facebook, it’s using tracking pixels to collect what you’re browsing. For its microtargeting to work, for its business model to work, it has to remain a surveillance machine” (Jacoby, 2018).

One component of Facebook, the “People You May Know” feature, is designed to allow users to add people to their social network. The feature relies on an algorithm that looks at a user’s friend list, education and work information, and their friends-of-friends, but also address books, work email addresses, and—despite public claims to the contrary—locations and IP addresses to make friend recommendations (Hill, 2018a). Facebook has also used targeted ads with information that was not directly provided by or revealed to users, and those users remain unable to view or delete their information, or even prevent advertisers from using their data (Hill, 2018b).

Facebook executives were questioned by members of Congress about the company’s privacy policies following the Cambridge Analytica scandal that exposed the personal information of more than 50 million users. In short, a personality profile app that was designated for academic use harvested information from individuals who took the survey—as well as information from their friends’ profiles—without their knowledge (Granville, 2018). This was, in essence, a hidden usage of public data whereby user information migrated from the clear web to the deep web.

The continued negligence by Facebook in taking adequate action to prevent additional breaches of security has resulted in a potential fine of \$1.63 billion under new E.U. privacy laws (Schechner, 2018). In December 2018, the British Parliament released internal documents from Facebook showing the company collected call records and text messages without user permission (Kirka, Bajak, & Ortutay, 2018). Company emails showed the move was acknowledged as “a pretty high-risk thing to do from a PR perspective” (Satariano & Isaac, 2018). The documents also revealed that Facebook white-listed certain companies such as Airbnb, Lyft, and Netflix, giving them preferred access to consumer data that other companies were not allowed to access following a policy change.

A recent Pew Research study following the Cambridge Analytica scandal showed that 42 percent of Facebook users had “taken a break” from the platform in the past 12 months, while 26 percent deleted the app from their phone altogether (Perrin, 2018).

Internet of Things

The Internet of Things (IoT) refers to everyday objects being able to send and receive data through the internet. Verizon estimates there will be 30 billion IoT devices by 2020—more than triple the number of devices in 2014; the “potential value generated” by IoT in 2025 ranges from \$3.9 trillion to \$11.1 trillion (Jalali, Kaiser, Siegel & Madnick, 2017, p. 3). Ownership of that data is complex, as data is generated by a user’s actions and could be considered theirs, but is produced and analyzed by the manufacturer of the product (Saarikko, Westergren, & Blomquist, 2017).

The appeal of IoT devices revolves around convenience and improving daily life (Green, 2017). At the same time, these sensing devices have been characterized as posing “an unprecedented threat to individual privacy,” as users “become targets of data collection without even noticing it and in hitherto unsuspected situations” (Lopez, Rios, Bao & Wang, 2017, p. 47). The authors concluded that legal protections against privacy intrusions on such devices remain limited. This is troubling given that IoT’s “security track record has been extremely poor,” as many devices lack the ability to be patched, leaving

them “permanently at risk,” and that problem is expected to become “more widespread and intractable” as the cost of making a device “smart” (Ranger, 2018, n.p.).

Such data is typically stored via cloud computing, where individuals and organizations store data on servers owned by third parties which may have “different agendas, responsibilities and vulnerabilities” and therefore “adds another layer of complexity” (Kernighan, 2017, p. xii). Furthermore, because personal data is frequently transmitted beyond the country of origination, it has been posited that “data havens could emerge similar to tax havens” whereby firms are able to store data in parts of the world with diluted privacy regulations (Newman, 2015, p. 508). The public cannot readily access this collection of IoT data, and that opacity is emblematic of information on the deep web.

Viewed holistically, what many people might view as routine activities—checking the weather, logging into the Facebook account, setting a timer through a home assistant like Alexa or Google Home, or simply walking around with a smartphone in their pocket—all function to generate a highly detailed view of consumer behavior. These user activities therefore frequently overlap and interact with corporate interests in acquiring consumer data.

CORPORATE DATA COLLECTION

There is growing corporate interest in Big Data, a trend that dates back to 2011 (Burrows & Savage, 2014). While there is no agreed-upon definition of Big Data, the National Bureau of Economic Research identified “new” aspects of it as data being “available faster, [with] greater coverage and scope, and includes new types of observations and measurements that previously were not available,” with “less structure, or more complex structure” than traditional data sets (Einav & Levin, 2014, p. 3).

Businesses frequently acquire and store consumer data before determining how to use the data that is being collected (Mayer-Schonberger & Cukier, 2013). Similarly, marketing practices that use consumer data have outpaced academic scholarship on the subject (Martin & Murphy, 2017). Data brokers acquire, store and sell consumer data. The FTC examined the databases of data brokers and found one had information regarding 1.4 billion consumer transactions, another had information on more than \$1 trillion in consumer transactions, another adds three billion new records each month, and a final data broker had “3,000 data segments for nearly every U.S. consumer” (Ramirez, Brill, Ohlhausen, Wright & McSweeney, 2014, p. iv).

In 2017, Congress repealed regulations that prevented internet service providers from selling personal information, giving those companies “free rein to do what they like with your browsing history, shopping habits...location, and other information” while also preventing the FCC from establishing privacy protections in the future (Wheeler, 2017). The editorial board of *The New York Times* argued that without stronger privacy regulations, more sophisticated users might rely upon virtual private networks and other privacy-enhancing tools, but “most Americans are unlikely to be conversant with such tricks of the trade” (2017).

European consumer groups have filed complaints alleging that Google used “deceptive design and misleading information which results in users accepting to be constantly tracked,” as it tracked, collected and aggregated users’ movements (Porter, 2018, n.p.). This follows a lawsuit in the U.S. that accused the search engine of tracking the location of smartphones even when the location history of the phone was turned off (Farivar, 2018).

Finally, in what could be possibly described as malevolent action by digital companies, there have been mainstream media reports that gather anecdotes from users who believe smartphone devices have

recorded their offline conversations (Langone, 2018; Hill, 2017). Whereas some vocal triggers, e.g., “Hey Siri,” will activate a microphone, Facebook and Instagram are thought to have thousands of potential triggers that would periodically allow the platform to access a user’s microphone (Nichols, 2018).

GOVERNMENT SURVEILLANCE

In the month following the terrorist attacks on September 11, 2001, the U.S. federal government passed The USA PATRIOT Act of 2001 in an effort to enhance national security. The sweeping legislative act expanded the ways in which federal agencies could monitor the communication of citizens. Law enforcement officials could now legally track email and internet usage without meeting a probable cause requirement (Lee, 2003). While many provisions of the Act initially had sunset clauses that aided its initial passage, Congress has subsequently extended the vast majority of those elements that were set to expire, and those surveillance tools remain in use today.

In 2013, Edward Snowden, a contractor working for the National Security Agency, illegally leaked classified information that revealed the existence of various global surveillance programs operated by the NSA and other governmental agencies, and aided by telecommunication companies. The “scale, reach, and technical sophistication” of this surveillance was unknown to the general public, and “came as a surprise even to seasoned observers” (Bauman, et al., 2014, p. 122). The NSA required Verizon to deliver metadata from the phone calls of millions of Americans, and Verizon was instructed to disclose neither the order nor the request for those records; furthermore, the PRISM program gave the NSA direct access to the servers of Apple, Facebook, Google, Microsoft, Skype, Yahoo, and YouTube—with those companies assisting the government in its efforts (Lyon, 2014).

The information revealed by Snowden generated a sense of distrust toward intelligence agencies not only in the United States but other nations in the “Five Eyes”—Australia, Canada, New Zealand, and the United Kingdom—and elsewhere in Europe (Walsh & Miller, 2016). In addition to the clear implications for user privacy, the exposure of these programs was shown to have had a chilling effect on search patterns (Marthews & Tucker, 2017), the use of Wikipedia (Penney, 2016) as well as the expression of marginalized political viewpoints (Stoycheff, 2016).

MALEVOLENT ACTORS

Perhaps the most overt and obvious threat to personal privacy—not to mention the biggest financial risk for users—are malevolent actors.

Russian hackers were indicted for their attempts to influence the 2016 U.S. presidential election. There, hackers who have been caught by the government are often given the choice of going to jail or working for the Russian state (Matthews, 2015). It is believed that many governments will continue to recruit more cyber-criminals in the future, as rogue hacker operations are uncovered, with an expert arguing that “it would be no surprise if there are links, and it would be a great surprise if there were no links” between such criminals and state actors (McGuffin, 2018, n.p.).

North Korean hacking groups have engaged in the online theft of more than \$100 million, the majority of which came from the central bank of Bangladesh (Reints, 2018). The U.S. intelligence community has stated that adversaries had the ability to threaten critical infrastructure, as well as IoT devices (Ranger, 2018).

Malevolent actors target social media platforms as well. In April 2018, Facebook announced that “malicious actors” had scraped information from the public profiles of “most” of its 2 billion users, but didn’t disclose the identity of the actors, how data might have been used, or the precise number of people affected (Timberg, Romm & Dwoskin, 2018).

A recent trend by hackers is to engage in real estate wire transfer fraud. A hacker will typically send a phishing attempt to a real estate or title agent. If the agent clicks the link, the hacker is able to view emails and wait for an upcoming sale. The hacker then emails the client directly from the agent’s account with instructions to wire the funds to a fraudulent account—with no legal recourse for the client (Stevens & Dujanovic, 2018).

SOLUTIONS AND RECOMMENDATIONS

Some users may be of the belief that utilizing Private Browsing Mode allows them to navigate online spaces without fear of divulging personal data, yet it has been shown that such browser settings may still reveal private information about the user (Liou, Logapriyan, Lai, Pareja, & Sewell, 2016). Such features protect a user’s browsing history from those who have access to the device, but do not prevent online data tracking (Verger, 2018).

Google allows users to view the activity that has been archived by the company. Users can then “filter by date & product” to view, for example, all of the voice interactions with Google Home and other devices (“My Activity,” n.d.). Facebook users are able to view advertisers that target them by navigating to “Settings > Account Settings > Ads > Advertisers You’ve Interacted With and then check out the section called ‘Advertisers who uploaded a contact list with your info’” (Horaczek, 2018).

The Tor Browser has prioritized user privacy, and operates in a slightly more decentralized fashion than a virtual private network. While the browser was considered to be usable only by relatively sophisticated users, a September 2018 update revamped the user interface, making it more inviting to a broader base of users (Nield, 2018). Even some of the most sophisticated users who combine a TOR browser with a Virtual Private Network connection to a reliable provider do not enjoy complete privacy protection, as users of TOR have had their identities revealed, and “VPN providers aren’t necessarily beyond the reach of law enforcement” (Mathews, 2017).

The Electronic Frontier Foundation, a nonprofit digital rights group, has established a webpage for users, who—with a single click—can determine how well their existing browser blocks online trackers (“Panopticklick 3.0,” n.d.). It also created a free Privacy Badger plugin, which blocks invisible trackers that pass through most popular web browsers (“Privacy Badger,” n.d.). The search engine DuckDuckGo does not track users, and has taken the stance that “The internet shouldn’t feel so creepy and getting the privacy you want online should be as simple as closing the blinds” (“Welcome to,” n.d.). The privacy-friendly search engine experienced record-high usage in 2018, due in large part to highly publicized data breaches (Lacy, 2018).

The Mozilla Foundation generated a list of dozens of common IoT devices, assigning them an aggregate score of “not creepy,” “a little creepy,” “somewhat creepy,” “very creepy,” or “super creepy,” based on what the device knows about the user, the degree of user control, the company’s responsiveness to consumers, and potential worst-case scenarios (“Privacy not included,” n.d.).

FUTURE RESEARCH DIRECTIONS

The Privacy Paradox has been explored a fair amount in recent years, with Barth and de Jong (2017) suggesting that it may be time to bifurcate online privacy research between stationary online use and mobile use. Future studies should consider that self-reports on privacy practices tend to be unreliable, particularly when accounting for events that are infrequent, so actual evidence of particular behaviors rather than self-reports is likely to yield the most insight into consumer behaviors (Kokolakis, 2017).

Perhaps another path forward in Privacy Paradox studies is to develop a standardized baseline for consumer privacy protection behavior. There may be a chasm between what an online user considers to be reasonable privacy precautions--perhaps through inaction, e.g., not responding to blatant phishing attempts, or avoiding websites that browsers mark as “unsafe” --and what researchers would characterize as proactive privacy protection measures.

Organizations could undertake efforts to clarify and simplify the terms and conditions for consumers using their websites and apps. Aside from ethical considerations, there are financial incentives for companies to embrace consumer privacy. Recent research demonstrates that firms which prioritize the privacy of consumers in a way that is deemed “authentic” will reap benefits including a “favorable market response, customer loyalty, and engagement” (Martin & Murphy, 2017, p. 152).

In terms of potential legislative remedies, the United States has a system described as “fragmented” and “patchwork” with “stronger protections for video rentals than online marketing, and lacking a regulatory body capable of dealing with present-day demands for privacy protection (Newman, 2015, p. 507). In light of this, some states have acted to bolster online privacy for users. California passed a law that will take effect in 2020 which grants consumers “the right to know what information companies are collecting...why they are collecting that data and with whom they are sharing it,” as well as giving consumers the right to demand that companies delete or not share their information without it impacting the quality of service provided by the company (Wakabayashi, 2018, B1).

CONCLUSION

The disclosure of a company’s privacy policy is viewed as an alternative to government regulation (Reidenberg, Breau, Carnor, & French, 2015). But it is not reasonable to expect consumers to read the privacy policy of each website they visit, as the time it would take to do so exceeds the total amount of time people spend online (McDonald & Cranor, 2008). In short, “something isn’t quite right with the whole system” and “shifting more of the responsibility to the websites who profit off your data might be a good way to start fixing it” (Wagstaff, 2012).

There has been a noted “creepy factor” of collecting personal information, as many consumers consider it an invasion of privacy (Kshetri, 2014, p. 1137) and users have described themselves as feeling “unsettled knowing their every click and ‘like’ is tracked, quantified—and sold” (Zomorodi, Poyant, & Aaron, 2017). Indeed, the confluence of digital technologies and Big Data has been referred to as “uncontrolled electronic panopticism” (Smith & Kollars, 2015, p. 160).

A bit of good news is that people who have fallen victim to an internet scam are more likely to build knowledge about the potential severity of the issue, and take account of the online spaces in which they remain vulnerable to further attack (Chen et al., 2017; Mohamed & Ahmad, 2012).

The future of internet privacy in the era of Big Data is uncertain, though there is a reasonable cause for concern. China has unveiled a social credit system that combines bank account information, court

records, and internet search history, combined with facial recognition, gait analysis and voice recognition with the stated goal of “allow[ing] the trustworthy to roam everywhere under heaven while making it hard for the discredited to take a single step” (Chun, 2018, n.p.). Meanwhile, India has a biometric database, Aadhaar, that contains digital identities with fingerprints and iris scans of more than one billion residents, though it has proven vulnerable to hacking as well as more mundane security breaches, as a group of journalists were given full administrative access to the database for less than \$10 (Cameron, 2018).

The risks to individual privacy online are greater today than they were 10 years ago, and those risks are likely to increase in the years ahead as more users—consciously or unwittingly—become more connected through apps, social media platforms, and the Internet of Things. The information age was once thought to characterize a knowledge-based society, but it may also come to be viewed as characterizing the behavior of corporate entities and malevolent actors who are driven to generate and extract private data from members of that society.

KEY TERMS AND DEFINITIONS

4

Big Data: A data set this is too large for “standard” software programs, and is generally used to identify large trends, and predict behaviors and outcomes.

Cloud Computing: The use of remote servers via the internet—rather than a local server or personal computer—to store and process data.

Cookies: Small text files that are placed on a user’s web browser as they visit a website.

Data Breach: An incident where information is accessed without authorization.

Internet of Things: A network of physical objects embedded with sensors that enable them to collect and share data.

Phishing: An attempt to obtain a user’s sensitive data through the use of a fraudulent identity via electronic communication.

Privacy Paradox: Individuals often claim to be concerned about threats to their privacy, yet do not act to protect their personal information.

Private Browsing Mode: A privacy feature in web browsers that disables a user’s browser and search history.

Protection Motivation Theory: This concept attempts to explain the way in which individuals react to perceived threats, and holds that individuals consider the perceived severity and probability of a threat, as well as the efficacy of their potential response.

Virtual Private Network: A technology that uses an encrypted connection to add security and privacy to private and public networks.

Societal Safety and Preservation in the Digital Era

Dylas Gudoshava

Zimbabwe Open University, Zimbabwe

INTRODUCTION

Personal privacy is being eroded from various directions as modern technologies bring numerous threats towards personal privacy. People are often unconscious about it and accept violation of privacy to a great extent without questions. Technological advancement has been embraced by all nations including developing countries. Today, the world is like a village where people share information at the same time but in different parts of the world over the internet.

Developing countries venture into new technologies without understanding the implications and the legal frame works under which the technologies operate. According to the 40th International Conference of Data protection and Privacy commissioners (2019), the technological pace keeps accelerating while the legal pace remains particularly slow. For this reason, developing countries may not effectively deal with crimes committed over the internet or in the office work environment. Spammers for instance, may send spam over the internet with little or no knowledge of users in developing countries. Although these countries may have laws on data protection, these laws are general in character and may not apply in crimes like spamming. Palfrey (2005) explained that, some countries use existing laws of general application to fight crimes like spam. Unfortunately, an observation made in 2005 still stands in 2019 as these laws miss their target.

BACKGROUND

Privacy and security are related, hence go hand in hand. The major difference being between legitimate and illegitimate uses of data. An illegitimate use of data is one that is unauthorised, that is, when data is stolen, altered, or viewed by the wrong party. This is the domain of security, which protects data from being inappropriately accessed, modified, or shared. Legitimate uses of data are those that have been authorised. However, in a discussion of privacy, there are plenty of legitimate data uses that may be problematic or harmful. For example, in countries where companies can collect individuals' data with only nominal notification, requiring users to search for ways to opt out, personal data can be used in ways that people did not expect or knowingly give permission to. This is the domain of privacy, which is broadly concerned with how people control and manage data about themselves. In essence, just because something is legal doesn't mean it is constructive.

Today's Internet age is marked by tremendous technological developments which allow for the collection and processing of an indistinct number of personal data. Before the advancement of technology, these data would have simply elapsed. However, with the advent of limitless capacity to store information, such as the cloud, google drive as well as digital space, there has been an increase in capacity of analysing and processing personal data. Personal information of daily life that is isolated does not necessarily

DOI: 10.4018/978-1-5225-9715-5.ch050

endanger personal privacy, however, put together, all this information allows for the creation of profiles of one's personality and such digital biographies increase vulnerability with regard to a variety of dangers. The right to privacy and the right to data protection have thus become two of the most important fundamental rights of modern society. Developments in the field of privacy require an innovative legal and political framework which can guarantee that the technological implications are correctly understood and regulated accordingly.

The Editorial Board (2017) describe Internet privacy as “involving the right or mandate of personal privacy concerning the storing, repurposing, provision to third parties, and displaying of information pertaining to oneself via the Internet”. It has to be noted that Internet privacy is a subset of data privacy.

Wheeler (2017) noted that “Privacy can entail either Personally Identifying Information (PII) or non-PII information such as a site visitor's behaviour on a website. PII refers to any information that can be used to identify an individual. Age and physical address alone, for example could identify who an individual is without explicitly disclosing their name, as these two factors are unique enough to typically identify a specific person. Some experts such as Steve Rambam, a private investigator specialising in Internet privacy cases, believe that “privacy no longer exists”. He notes that “Privacy is dead – get over it” (Rambam, 2015).

While illegitimate uses of data must be contested with security, legitimate but harmful uses of data must be interrogated through the lens of privacy preservation

The penetration of Internet throughout the world is bringing an increase in volume of user information online. Developing countries such as those of Africa are included as contributors and consumers of this voluminous information. Concerns have been shown from different parts of the world regarding Internet user privacy and security. For Southern African region, very little is known regarding how Internet users are concerned with their online privacy and security. This chapter aims to compare Internet user awareness and concerns about online privacy and security between users in a developing country and users in a developed country, and to determine any common attitudes and differences between these user groups.

Retreating to one's home, closing an office door, or hanging up a phone may have previously allowed a person to feel a measure of control over who might be listening or watching, but the presence of network-connected devices in private spaces can remove this sense of control and privacy (Rosner and Kenneally, 2017). In an article by Fick and Akwagyiram (2019) in the Nairobi/Lagos Reuters, it was noted that “in Kenya, there is a large and fast growing population of internet users”. At the same time, there are no specific laws or regulations to protect the privacy of those individuals. Recent revelations about British analytics firm Cambridge Analytica, which Facebook says improperly accessed personal data of about 50 million of the social networks users in the 2016 U.S. presidential election, have also touched the African continent.

Fick and Akwagyiram (2019) noted that “Kenya is not alone in Africa, which as a region has clocked the world's fastest growth in internet use over the past decade”. Unlike in Europe and the United States, where data-privacy laws provide a level of protection to consumers, many Africans have little or no recourse if a data breach occurs because often legal and regulatory safeguards don't exist. In an article by Kshetri (2019), he observed that there were 24 million malware incidents that targeted Africa in 2016. In a survey conducted in Ghana, it was noted that “in 2016, Ghana's financial institutions were reported to experience more than 400,000 incidents related to malware, 44 million related to spam emails”.

Some economies in the continent are becoming attractive to cybercriminals, thanks to the high degree of digitisation of economic activities. For instance, 86% of South Africans regularly use online banking services. This proportion is higher than many countries in the Middle East and Turkey.

The chapter seeks to answer research questions that follow:

1. What are the laws that are currently in place (if any) to protect user's online privacy?
2. What are the potential barriers to greater online privacy protections?
3. What measures are available for users to have greater online privacy protection?

The research objectives are:

1. To find out the laws currently in place (if any) to protect user's online privacy;
2. To determine potential barriers to greater online privacy protection; and
3. To determine measure that can be taken by internet users to have greater online privacy protection.

As online privacy has become an issue of concern around the world, findings from this study would be beneficial to the policy makers in developed and above all developing countries. Findings could also result into awareness projects in developing countries that sensitise people by creating awareness and understanding about online privacy risks and their impacts in Internet users' offline lives. To the future author, this chapter provides relevant information on user perception of privacy and security in developing countries.

REVIEW OF LITERATURE

In a study done 4 years ago by Ruhwanya (2015), he noted that "the Internet has shaped the way information is stored, shared and distributed around the world". As mentioned above, today's Internet age is marked by tremendous technological developments which allow for the collection and processing of an indistinct number of personal data. Before the advancement of technology, these data would have simply elapsed. However, with the advent of limitless capacity to store information, such as the cloud, google drive as well as digital space, there has been an increase in capacity of analysing and processing personal data. Over the years the advent of google, personal data is among the main driver of today's Internet world especially the social network sites. Social network sites such as Facebook, Twitter, LinkedIn, blogs and picture sharing sites like Instagram and Flickr are driven by user provided information. It has to be noted that Social networking sites in particular are the biggest source of personal information, often unprotected and publicly available (Yanisky-Ravid, 2014). As the amount of online user information increases, privacy has become an issue of concern. User information is sometimes used in decision-making (Nani et al, 2012): for instance, employers can conduct background checks on potential employees from social network sites and use that information to make hiring decisions. As people share their own personal information, websites do track users' browsing behaviours, from browser cookies sometimes without website users' knowledge or consent (Cranor, 2004). Information which is obtained from tracking user behaviour online is used to profile users as well as provide targeted advertisements by marketing and advertising companies.

The advances of Internet and database technology has led to an increase over information privacy concerns (Chung & Paynter, 2002). Data which is entered into forms or contained in existing databases, can be easily combined with transaction records and records of an individual's every click of a mouse on the Internet. Chung & Paynter (2002) further note that "privacy concerns increase further as data mining tools and services become more widely available". Cookies are now widely used to identify users at a web site, some people consider this to be invasion of privacy.

The user will be prompted for information such as buying preferences, age, gender or even an email address. As an example, If one I buying a book from Amazon.com, one will be prompted to enter email address, billing address and other information. The information will be packaged into a cookie and sent to the user's hard drive, which stores it for later user identification. The user's browser will send the cookie to the web server when the user goes to the same web site. The web server can utilise the information in the cookie to generate customised web pages according to the interests and preferences of the user, hence information about one's movement in a web site can also be stored in a cookie.

The main concern is that all this is done without one's knowledge. By using cookies, businesses can obtain personal information such as buying habits, e-mail address or the portions of web site that were looked at previously. This information can be combined into mailing lists for direct marketing purposes or it can be sold to third parties. James (2000), noted that "America Online shares information about its users with various partners, including companies that do direct mailing and telephone solicitations".

A web bug is another widely used instrument that poses a threat using online tracking technology. Some people find it invasive to their privacy when they are visiting a web site. Web bugs are invisible pieces of code that can be used for several purposes, from secretly tracking people's web travels, to pilfering computer files (Stefanie, 2001). The simplest form of web bug is a small graphic interchange format that can work and match with cookies to send information to third parties about a visitor's online travels. An executable bug can install a file onto people's hard drives to collect information whenever they are online. A script-based executable bug can be installed on a user's computer that can take any document from the user's computer without notice. Another form of script-based executable bug is based on servers. They can track visitor's travels on the web and control the person's computer from its server. For example, it launches multiple browser windows when a person tries to exit the site. Many web sites and net advertising companies place web bugs on their pages to collect information, such as which pages are being read most often (Stefanie, 2001). As mentioned earlier, the bugs can be used in a more invasive way, for example, to capture a visitor's Internet Protocol address or installing pernicious files in the visitor's hard drive. The concern is that with a web bug, the visitor's computer can be fully exposed to malicious sites that can take any files or information from programs on the visitor's hard drive without their knowledge and consent.

A report shows that 16 million pages out of 51 million that were scanned contain at least one web bug that had been attached from a third party, such as an advertising network (Stefanie, 2001). When web bugs are used maliciously, the computer user's entire e-mail address book can be stolen without notice merely by clicking on a bugged web page.

Another privacy concern is that marketers can match their customer databases with the databases they get from the cookies. DoubleClick had already built up a database of online consumers' browsing habits by using cookies. It paid Abacus Direct Corporation. \$1.7 billion for the list of catalogue purchasers' names and addresses (Cattapan, 2000). This allows cross-referencing that matches information with real world names, addresses and histories of offline mail order purchases (Anstead, 2000). The acquired names and addresses can be linked with the cookies so DoubleClick not only knew where people are online, but where they live, who they are, and their phone numbers. This could be the most comprehensive customer database in the world that can be used for direct marketing purposes.

What Are The Laws Currently in Place (if any) to Protect a User's Online Privacy?

Privacy law refers to the laws that deal with the regulating, storing, and use of personally identifiable information of individuals, which can be collected by governments, public or private organisations, or other individuals. Over the years, online activities have become progressively more public. Part of this is related to online social networks and the blurring of the line between public and private (Vitak, 2012). Not surprisingly, people have started to become aware that they have little expectations of privacy online and are calling out for more privacy protections (Risen, 2015). Only in 2016 was the Electronic Communications Act of 1986 in Australia revisited (Kelly, 2016) in light of new technology, even when advocates have long stated that the language is outdated (Sidbury, 2001).

Access to Information and Protection of Privacy Act (AIPPA) was enforced in 2002 by the Zimbabwean Parliament. AIPPA was inspired by the Canadian Information Legislation. It sought to provide a legal framework for the access and conduct of requesting information from public bodies and privacy as well the regulation of mass media. According to the Act, only citizens of Zimbabwe, permanently residents or holders of temporary employment, residence permit or student permit are eligible to make request (2002). However many critiques such as David Banistar stated that AIPPA is a rather sceptic name for a media suppressing law.

Zimbabwe's constitution enacted in 2013 explicitly recognises the right to privacy (Section 57):-

Every person has the right to privacy which includes the right not to have:

1. Their home, premise or property entered without permission;
2. Their home, premise or property searched;
3. Their possessions seized;
4. The privacy of their communications infringed; or
5. Their health condition disclosed.

In a post by Makokoba, W (2018), he noted that “although the right to privacy is stated in the constitution, Zimbabwe is one country without clear Personal Data Protection law, literally, people's information is liable to wrong use”.

This leads to the second research question.

What Are the Potential Barriers to Greater Online Privacy Protections?

The answers to these questions still do not offer much to the user in terms of privacy management when they are not highly considered to be the frontier discussions. This is so due to the ever evolving technologies. This leads to the question about measures available for user to have greater online privacy protection. This area will be addressed by examining the state of technology today, online platform business models, and potential governmental interests in the state of internet privacy.

What Measures are Available for Users to Have Greater Online Privacy Protection?

This research question will be addressed by briefly looking at the major current privacy laws in both developed and developing countries. In addition, the rules currently governing the institutions involved

with user privacy agreements will be examined. A detailed list of methods that users can employ to protect their own privacy when institutions fail to protect their privacy rights will be drawn up. These methodologies include both technical and social solutions to protecting online privacy.

CHALLENGES

Technological Advancement in Information and Communication Technology

A lot of progress has been made in discovering new knowledge in the field of information and communication technology. Some of the new knowledge and advancements have been used for the wrong reasons. For instance, hackers use their high-tech skills to change, intrude or interfere with computer networks with an intention of destroying information or making some money out of it e.g. a banking fraudulent deal. Bullesbach (2004) notes that, “development and application of new information and communication technologies lead to challenges of data protection”. Although new technologies in developing countries are a positive move to development, planning is necessary before applying new knowledge. Hackers use principles of new technologies. It should be noted that hackers may indeed be consultants in the particular firms they are working for. It means that such crimes may go undetected or can be detected after a long time. The reason is that the consultant (hacker) occupies a position of trust and nobody would suspect any ill motives in his or her operations.

Capron (1996) explains that, most computer crimes are discovered by accident. Capron (1996) identified a case in which employees of a certain city welfare department created a fictitious workforce and programmed the computer to issue pay cheques, which the employees would intercept and cash.

Spamming is a crime that is also linked to technological advancement in the field of information and communication technology. The current explosion of mobile phone communication and cheap email services has attracted a lot of spamming activities. Palfrey (2005) observed that, spam is the preferred delivery mechanism for internet security threats such as viruses which harm computers and phones. The effects of those in developing countries are largely to persuade users to begin to rely on digital communication. A Kenyan lawyer, Mathew Ngugi observed that the massive gains brought by the information age are not perfect (Ngugi, 2005). This clearly illustrates how the economies of developing countries continue to suffer as they apply new technologies.

Developing countries lack specialised personnel who can effectively deal with advanced computer crime. Computer crimes have become more pronounced and more complicated to the police due to expansion of internet communications (Wikipedia, the free encyclopedia, 2006). This challenge is technological in character which can be associated with the curriculum offered to police officers during their training. They have no training based on information technology and that is why an investigation on computer crime is bound to yield no result as the investigator is not well equipped with current technology based investigative procedures. If law enforcement agents like the police detect a computer crime, Capron (1996), observed that “they do not fully understand the complexities of computer related fraud”.

In an article by Rosner and Kenneally (2017) they noted that “When users of a smart device are presented with a full privacy policy at the outset, these long, convoluted contracts often leave consumers with little understanding of what they are consenting to”. They further highlighted that many companies that capture personal data are not even certain about what they will do with this data in the future, reducing users’ ability to be fully informed about potential uses of collected data. The issues are worse off for devices designed for children. This makes it difficult for parents to protect their children’s privacy.

However, it is widely accepted that most people do not read privacy policies. This therefore means that, parents risk making their children's play and behaviour visible to many third parties, and neither they nor their children are likely to be aware of this.

Inappropriate Legislation and Inadequate Internet Regulations

Inappropriate mechanisms to data protection have hampered data protection in developing countries. Laws on data protection and privacy are there but are not specific to the target. General laws such as consumer protection are largely utilised (Palfrey, 2005). Consumer protection is a general term that can imply personal security against physical injury. There are a lot of inadequacies in the Zimbabwean legislation on data protection which is also expected to be the case in other developing countries. A Kenyan lawyer, Mathew Ngugi observed that, there is lack of analogy between most cyber crimes and their conventional counterparts (Ngugi, 2005). He compared trespassing and hacking into a computer network. The penalty on trespass does not hold against hacking and accessing private data. This clearly illustrates a challenging situation whereby no relevant laws on hacking are available.

People in developing countries are widely using the internet. Though convenient, there are few sufficient regulatory mechanisms on data access. Makokoba (2018) cites Zimbabwean government, as not being able to do much to censor the internet. Instead, the government limits access to internet. This significantly illustrates how developing countries want to benefit from new technologies without laying a proper foundation of regulatory procedures on data protection. Froomkin (1996) in his study of internet access in Singapore noted that "information deemed obscene (pornography) in one jurisdiction may be legal elsewhere". This illustrates the conflicting legal provisions of internet regulation for different countries.

Censorship is an important aspect of internet regulation. Governments' legal structures have been challenged in court. For instance, the Zimbabwe government was challenged by private mobile phone providers through a high court order restraining the government from controlling the information gateway system for the providers (Africa.aspx, 2006). This illustrates how data regulatory mechanisms in developing countries are still in want

Unethical Computer Use in the Office or Business Atmosphere

Ethical practices in the work environment form the basis of success for any business venture. Boulton (ud) observed that "employees in small business firms are likely to pirate software, a practice that is seemingly endorsed by the management for purposes of business survival". The main challenge here is piracy within the office/business atmosphere where the superiors may not regulate their users. Otherwise, there may not be clear guidelines on ethical practice in the office. Piracy of data is practiced by experts with the necessary technical knowledge. For example, IT (Information Technology) consultants may use pirated software to complete certain projects. Some firms accept projects that involve software they cannot afford to purchase and seek illegal means of obtaining such software (Boulton, ud). Developing countries experience this problem because of the increasing unemployment trends, where people survive by using illegal business practices to make a living. The use of the internet in the office acts as an entry point to pirated software. Illegal transactions can be carried over a network without being noticed. For example, Froomkin (1996) observed that, trans-border gambling can go on over the internet, evading regulations imposed by jurisdictions in their countries.

Ethical use of computers in the office is challenged by lack of proper guidelines on privacy. Invading a computer to find out what an employee is doing is interfering with his privacy. On the other hand, restricting internet use in the office is different (Weckert, 2000). For example, a survey carried out in three different companies situated in Nairobi, Kenya on employee monitoring, of the employees interviewed, 50% said that they were being monitored secretly when working with the computer, 30% felt that work ethics should guide a person and not monitoring from superiors and 20% felt that monitoring was okay only if it is objectively done. This illustrates the state of affairs in developing countries implying that there are no clear guidelines on privacy and information access at work place. This challenges the employee who should be an agent of privacy at work place. This is why; Bynum (2000) explains that, there are always problems in the application of computer ethics because there are no clear policies of how computer technologies should be used.

Computer System Mal-Function And Hardware Failure

Data should not only be protected from people (users) but also from computer systems that either not functioning well or hardware that fails to function appropriately. System operations are related to the software used. System failure, according to Meadowcroft (2005), may result from the complexity of the software used. Developing countries are using modern software which is more complex and efficient in operation. If there is improper coding of software, the system is likely to fail. Data held in such a system is also likely to vanish if the system malfunctions. System failure can result from the user e.g. when the user gives the computer inaccurate instructions. This may lead to loss of files and indeed data held in these files (Capron, 1996).

Certain types of hardware such as diskettes are vulnerable to conditions such as extreme temperatures, scratching, pressure and presence of magnetic fields (Capron, 1996). As such, data in them is likely to be lost because of such conditions. This is common in developing countries because the hardware being sold to consumers is of low quality and quite susceptible to the said conditions.

Identity Theft and Credit Card Theft

Cameron (2018), noted that “data reveals the global circulation of stolen identities is leading to major shifts in cybercrime worldwide, with developing countries cultivating newly formed internet-based economies responsible for a generous amount of fake and stolen account activity”. Notably, as e-commerce markets in Latin America continue to expand, incidents of fraud are beginning to skyrocket. Stolen and forged identities used to create fake accounts is, in turn, becoming a market unto itself. It has to be noted that billions of online users are generating huge amounts of personal data and this makes it easier for cybercriminals to steal and monetise this. Data which has been stolen gives cybercrime a deceptive mask, as they take over identities to open new accounts, takeover legitimate user accounts or perform fraudulent transactions.

Cameron (2018), noted that “in the first quarter of 2018, researchers registered more than 150 million rejected transaction, indicating online fraud is soaring; the figure represents an 88 percent increase from the same period in 2017”. Moreover, new and emerging economies Egypt, South Korea, Ecuador, Ukraine, and Vietnam, are offered as examples, have contributed to 820 million bot-based attacks targeting ecommerce sites worldwide (Cameron, 2018).

The challenges having been looked at, the chapter will continue to look at the arguments for and arguments against internet privacy.

REMEDIES TO THE CHALLENGES

Internet Regulations for Both Users and Internet Service Providers

New technologies contribute to the national development of developing countries. However, challenges due to the technological advancement retard the growth of some sectors of the economy. Internet access is one of the main issues. Developing countries need to initiate self regulation mechanisms. Bullesbach (2004) observed that “adequate data protection is effective when countries initiate data protection by means of self regulation”. This is an important aspect for developing countries because of the different cultural diversities of their people. Self regulation mechanisms would cater for all diverse cultures different from the western countries. Palfrey (2005) observed that “internet service providers must be encouraged to establish codes of conduct that prohibit their users from using the internet to access illegal information or doing illegal business transactions”.

Developing countries should embrace a self regulatory approach by encouraging their internet service providers to regulate their customers by establishing regulatory mechanisms internal to their businesses. This would cultivate ethics among customers in using the internet. Spamming can also be controlled by using combined efforts between law enforcement agencies and internet service providers. Instead of chasing spammers, according to Palfrey (2005), regulators in less developed countries can only succeed by working in liaison with internet service providers who are closer to the source of the problem i.e. their customers and the technology in question. Due to the complexity of spamming, developing countries can avail resources and the necessary personnel to help combat spamming.

The primary role of data access and protection lies with the users. The users must be ethical in accessing data. Unethical users need to be legally regulated. This is why; Barroso (2001) cited that “internet use should be legally regulated besides having the users’ role in its regulation”.

Computer Ethics Education and Training Among Users

Ethical practices are an important component of any professional field. In this era of Information and communication technology, a lot of data relating to people, governments and business organisations is being handled by computing professionals. As a result a high level of ethical practice is essential. Ethical practices can be imparted to computing professionals during their course of study or being given in-service training. Weckert (2000) noted that “there must be involvement in the education of computing professionals”.

Ethical practices in developing countries should serve a central role in alleviating data crimes. Computer users in these countries should be trained on ethical issues related to data protection. There is a need for refresher courses on emerging issues such as internet pornography, spamming, hacking and other forms of cyber crime. All these issues are as result of the advancement in information and communication technology. The main remedy is therefore a code of practice for all computing professionals and service providers in information and communication technology. Not all computer-related infringements are noticed. This is why all computing professionals should regulate their practices in an ethical point of view. As Barroso (2001) noted “the cyber society in which we live needs an ethics of the internet and that internet ethics depend on the receiver or navigator”. As a result, internet service regulatory bodies and internet service providers can educate their customers about certain dangers of internet communication (Palfrey, 2005).

Personal data should also be protected from unauthorised access. A culture of personal data protection should be cultivated among users. Lace (2005) proposed that “people should be made aware of how to protect their personal data and resist any mal-practices involving their data”. The integrity of data depends on the end user. For instance, if a user is well trained, the chances of the system failing are greatly reduced which improves the reliability and integrity of data (Meadowcroft, 2005).

Computer ethics education requires a global approach for harmonisation. All stakeholders must be involved if meaningful solutions to computer ethics are to be provided. Weckert (2000) proposed that “a number of disciplines must cooperate so that meaningful answers to computer ethics are to be provided”. Employers must cooperate with their employees on matters of computer ethics. Cheung (2000) observed that “the induction of new employees to the culture is a central measure of data protection”. Since different organisations may deal with data differently, new employees need to be introduced to all aspects of data protection.

Cross-Border Harmonisation of Laws on Data Protection and Enforcement Procedures

Data protection requires concerted efforts which must involve harmonisation of new or existing legislation. These laws must have an international setting and applicable to all states regardless of whether a country is developed or not. Conflicting or no laws at all hampers the fight against illegal data access and cyber crimes. Developing countries need to establish common laws that can be uniformly applied in different countries for the same crime. Ngugi (2005) proposed that “there is a need to act in concert with the global community in combating cyber crime”. He further observed that, legislations on data protection should provide for dual criminality in case a culprit crosses borders (Ngugi, 2005). Relevant stakeholders in developing countries should therefore hold common forums within which certain laws can be harmonised. Harmonisation implies cooperation between different countries. Bullesbach (2004) noted that “international harmonisation of principles of data protection ensures international data transfers in global markets”. This implies that illegal data access will be minimised by use of common principles.

Cooperation could be evident when different countries’ law enforcement agents cooperate in fighting cyber crime. For example, the likes of Interpol. As Brenner (2001) observed, Interpol pursues cyber crime through regional working parties. Palfrey (2005) proposed that, harmonisation and collaboration are essential in fighting cyber crime. This could be an effective method of fighting cyber crime as it illustrates uniformity in law enforcement for different states. Conventions on internet crimes can also aid in fighting cyber crimes. For instance, the United States joined the Council of Europe Convention on Cyber crime on September 29th 2006 (McCormack, 2006). Developing countries should emulate the developed countries by joining such conventions. Froomkin (1996) observed that, without cooperation between the two governments involved, there may be very little the affected government can do to fight the crime. The same idea is applauded by Franco (2006), when he explains that, task forces on minimising piracy have helped stem out such crimes across the borders of Brazil, Paraguay and Uruguay.

Response to System Failure, Hardware Failure, and Power Blackouts

Data needs to be protected against physical factors such as system failure, hardware failure and power blackouts. System failure may depend on the users and this is why users have a central role to play to avoid system failure. The best practices for avoiding system failure, according to Phillips (2004), include user manuals that provide system specifications and also testing the code earlier in advance. Testing of

code is an ethical aspect of software development which affects the system functionality. Meadowcroft (2005) observed that “system testing is important in being prepared for potential system failures”. Developing countries should adopt an ethical culture of using sufficiently tested codes. This would improve data security. Users should also be trained on how to use particular computer system to avoid failure.

Faulty hardware can lead to data loss. To avoid hardware failure, essential functions could be transferred to backup components (Meadowcroft, 2005). Some types of software are also important in backup. Capron (1996) observed that “the use of software that automatically backs up all files is essential for data protection”. Power losses or power blackouts can lead to loss of data. Reliable power sources should be sought.

National Youth Development Forums and Self Employment Initiatives

Developing countries should view youth unemployment as the major source of the numerous economic crimes including data piracy. The youth should play an important role in data protection. Governments in developing countries should initiate forums that are aimed at educating the youth on self employment and also organising workshops for educated but unemployed youth. They should establish youth groups whose main objective is to eradicate data crimes. Such forums can be used to disseminate ideas on cyber crimes and the role of the youth in alleviating such cyber crimes.

Arguments for Internet Privacy Concerns

Consumers are really interested in the safeguard of their privacy. Surveys show that the primary reason most non-Internet users avoid the Internet is because of the concern about the privacy and safety of their personal information and communications (Federal Trade Commission, 1998). Privacy concerns prevent some consumers from buying products on the web. A marketing research firm, NFO Interactive, conducted a study in 1999 and found that almost three out of four consumers who browse the Internet never make any purchases online (James, 2000). Those consumers said that they would be more likely to buy if they could be assured that their privacy would be respected (James, 2000). A study by Satitkit (2001), on the travel sector in New Zealand suggested that “privacy and security were the concerns that stopped people from purchasing travel tickets online”.

Although personal information may not be used after collection, it must be noticed that collecting and keeping this information is a potential liability for a web site when it meets some consumers that take the safeguard of their privacy seriously. Internet based businesses should care about the privacy concerns because consumers care about it. Since businesses are developing relationships with consumers, it helps if consumers know that businesses care about them. People are more comfortable if they see a privacy statement, and are more assured if a privacy statement has been approved by a third party, such as TrustE [10, 24] (Satitkit, 2001). To boost the development of e-commerce, information privacy concerns should be treated seriously as these discourage consumers from using the Internet in buying goods and services (Federal Trade Commission, 1998).

Arguments Against Internet Privacy Concerns

To some people, Internet privacy concerns are not special issues, and some are just over sensitive as they realise that the Internet is growing. Shopping online is not different from in-store shopping as these both raise the same privacy concerns. Tracking a person’s navigation while online can be compared to

a camera spying on people while they are moving around in a store. Although cookies can be used to identify users to a web site, cannot find out names, addresses, and other personal information unless consumers have provided such information voluntarily (Cattapan, 2000). Thus, the use of cookies is not a main point regarding the privacy concerns. The Roy Morgan Research (2001) in its findings noted that “it is a fact that some people are willing to give away their personal information in return for discounts and other particular benefits. An example is the befoward platform for purchasing vehicles whereby one creates an account with personal information so as to get discounts as well as online news and alerts. The use of cookies for online purchases is not different from catalogue purchases by mail when personal information is provided voluntarily. They both raise the same privacy concerns that information may be misused when it gets to the hand of the businesses.

Another argument emphasises that Internet privacy concerns are trivial. Consumers do not want to reveal their information online for marketing purposes. Actually consumer information can also be found in telephone books or other sources. This information can usually be used by marketers for marketing promotions. Marketers can send flyers to physical letterboxes based on this information. It is argued that getting rid of junk email is easier than getting rid of junk physical mail. Thus, the privacy concerns regarding junk email are considered to be trivial.

Use of internet Regionally and Internationally

In a study by Ericsson Consumer Lab (2014), the growing adoption of smart phones in Southern Africa significantly increased Internet access within the local populations. The research study showed that “approximately 70% of Internet users in sub-Saharan Africa access the Internet through their mobile phones compared to 2% who use computers”. Access to social network sites such as blogs, YouTube, Twitter, Instagram, LinkedIn, and Facebook has also increased significantly. According to the Internet World statistics (2018) as of 31 December 2017, Estimated Internet utilisation in Zimbabwe was at 35, 2% while the rest of the world was at 58,4%. Internet users in Zimbabwe were estimated at 50 000 in 2000, while in 2017, estimated users were at 6 796 314. Compared to the Americas, Internet utilisation was at 100% with a total of 783 909 293 estimated people. This increase in Internet penetration and usage also increases concerns about online privacy. In developed countries such as USA, many studies have been conducted to assess Internet users concerns about privacy, but little is known for the Southern African countries.

Personal Data Protection Legislation

Deloitte (2017) notes that “many Internet users express demand for legislation that protects their privacy online”. Moreover, there are currently 17 countries in Africa that have enacted comprehensive personal data protection legislation, namely Angola, Benin, Burkina Faso, Cape Verde, Gabon, Ghana, Ivory Coast, Lesotho, Madagascar, Mali, Mauritius, Morocco, Senegal, Seychelles, South Africa, Tunisia and Western Sahara¹. In addition, the African Union (AU), adopted the AU Convention on Cybersecurity and Data Protection (AU Convention) in June 2014 (Rich, 2016). However, the AU Convention has not currently taken effect as it has, to date, not been ratified by 15 out of the 54 AU member jurisdictions (Rich, 2016). Nonetheless, the AU Convention does provide a personal data protection framework which African countries may potentially transpose into their national legislation, and encourages African countries to recognise the need for protecting personal data and promoting the free flow of such personal data, taking global digitalisation and trade into account. In this regard, Rich (2016) notes that “there

are three countries, namely Kenya, Uganda and Zimbabwe, which have already enacted personal data protection legislation, the promulgation of which has not yet been made effective, as the laws are still in the form of bills”. Tanzania is another country which is currently in the process of enacting personal data protection legislation (Rich, 2016).

An early study on general online privacy awareness and concerns was done by AT&T in 1998 (Cranor et al, 1999), with the aim of understanding how American user are concerned with their online privacy. The sample was drawn from the FamilyPC magazine/Digital Research, Inc. Family Panel to represent the future Internet population of the USA. The finding indicated that 52% of Internet users were concerned about web cookies, and among those concerned, 56% had taken measures to change their cookie settings to something other than accepting all cookies without warning (Cranor et al, 1999).

A more recent study on user concerns on Anonymity, Privacy, and Security Online was done by the Pew Research Center in 2013 (Ruhwanya, 2015). This study was directed to American Internet users and data was collected from telephone interviews among a sample of 1,002 adults. The study shows a growing level of privacy concern for Internet users, in practice, “86% of Internet users have taken steps online to remove or mask their digital footprints – ranging from clearing cookies to encrypting their e-mail, from avoiding using their name to using virtual networks that mask their Internet protocol (IP) address ” (Ruhwanya, 2015).

SOLUTIONS AND RECOMMENDATIONS

Most Internet users spread their own personal information and sign privacy policies without even giving it a second thought. This behaviour verifies the fact that people are oblivious about their own privacy. However, blame cannot be put on the end user, corporations must take responsibility when they formulate privacy policies so that the users understand the content of them and in particular explain how what they do with the information. Email is one of the most important and applied features on the Internet but the unrestrained growth of spam threaten its functionality. A solution to this requires cooperation between online actors, legislatives and educators. Overallly, there is a need for cooperative legislatives amongst countries within the five continents of the World. This will allow for uniformity.

FUTURE RESEARCH DIRECTIONS

A number of further questions arose during the study. It would be useful to conduct research for each developing country separately and take on a random national sample of the Internet users; study why some personal data are more sensitive in developing than to developed and vice versa; and study further why developed countries are more aware of measure to conceal online privacy than developing countries. This information would benefit Communication Regulatory Authorities in developing countries, who could adopt to the approaches and findings reported in this chapter to better understand their consumers’ behaviour regarding internet privacy and see how they can regulate the privacy policies to align with user needs.

CONCLUSION

The majority of the legal protections are laws that were enacted long before the Internet was commercially available and were just applied to the Internet as if it were any other technology. With no federal law protecting privacy on a universal level for adults, there is room for improvement. The burden of protecting online privacy has fallen to the user who is expected to read an obscene amount of text found in terms of use agreements and determine how to respond if they do not agree with the terms presented to them. If they do not agree, but have no choice but to sign or didn't read the terms until after they already signed the agreement they are left to using technological means to protecting their privacy. Overall, situation in regards to protecting online privacy in the United States is depressing. While there is most certainly room for improvement, it may take over a decade before any true progress is made. Until then, the best hope for privacy is that the technological protections outpace the threats to online privacy.

KEY TERMS AND DEFINITIONS

Developed Country: A self-governing country with advanced technological infrastructure, a developed economy as well as an advanced industry.

Developing Country: A country that is still seeking to become advanced in all spheres that is industrially, economically, politically, and socially.

Internet Privacy: This is the privacy and level of personal data and or information published online (via the internet).

Internet Utilisation: The amount of data flowing through a computer or device (mobile phone, tablet) for a given period of time.

Privacy Protection: The coexistence of the collection and dissemination of information communication technologies, what the public expects as well as socio-political and legal concerns bounding them.

Privacy and Security Challenges in the Internet of Things

INTRODUCTION

The Internet of Things (IoT) is a concept that describes the large and growing number of digital devices that operate between networks of potentially global scale. Unlike the conventional Internet, in which interaction is essentially performed by people, IoT is composed only of sensors and other intelligent devices (Chou, 2016). Therefore, we are facing a technological revolution that includes the interaction between objects and simple actions of daily life to the most complex processes of organizing entire industrial productions. IoT provides new and innovative ways for organizations to manage and monitor remote operations (Vermesan & Friess, 2014). Conceptually, it offers the possibility of connecting the physical world with the digital world through the Internet.

Significant social and material vulnerabilities can appear with the advancement of IoT. The Internet exposes people to new risk situations, which although they already exist in the physical world, are enhanced in the virtual world, due to the greater exposure and range that technologies provide. Several risks may arise due to IoT's lack of privacy and security. For example, hackers can open the door of a house remotely by knowing access security codes, can know user behaviors through access to the network of home light sensors or temperature sensors, can spy a person through access to security cameras, etc. (Eastwood, 2017; Karlov, 2017). Therefore, it is critical that IoT provides strong security mechanisms in a way that the benefits of this technology could be safely exploited by people.

The large network of connected devices and the enormous flow of data that IoT will generate turn data security and privacy a fundamental challenge. In this sense, this study aims to characterize how IoT service providers address the challenge of data privacy and security. By conducting case studies with leading companies in this sector we seek: (i) to identify the main privacy risks that IoT devices can expose; (ii) analyze the main privacy and security barriers in IoT devices; and (iii) propose counter-measures that can be adopted by companies and users to increase the security of IoT. The manuscript is organized as follows: initially a literature review on the concept of IoT and security and data protection is performed. After that, the adopted methodology is presented. Consequently, the main identified solutions and recommendations are presented and discussed. After that, some indications for future research are given. Finally, the main conclusions are drawn.

BACKGROUND

Concept, Evolution and Technologies of IoT

IoT is a concept in which the devices and objects of our day-to-day life are equipped with sensors capable of intelligently communicating between them. According to Hanes et al. (2017) a “thing” in the context of the IoT is a connected object which may be, for example, a person with a heart monitor, an industrial tank with level sensors, a car with sensors that warn of tire pressure, a public lighting of a city, an outlet at home, or any other natural or man-made object. IoT collects information from various devices (computers, vehicles, smartphones, traffic lights, etc.) and applications (anything from a social media application like Twitter to an e-commerce platform, from a production system to a traffic control).

IoT has the potentiality to transform the way we live, work and learn. It is the beginning of a cycle of technological renewal that will aid in the optimization and automation of basic daily tasks. In addition, it may bring important information for the public benefit, and for private companies to be more assertive in their products and services rendered. The virtual connection of data, people, processes and things promises to create a world of new economic opportunities, including Smart Cities, Smart Environment, Smart Metering, Security & Emergencies, Retail, Logistics, Industrial Control, Smart Agriculture, Smart Animal Farming, home automation and e-Health (Talari et al., 2017). For Kash (2014), some practical examples of IoT application are:

- Intelligent parking systems for cities will provide real-time visibility into the availability of parking spaces throughout the city;
- Teleworking can eliminate the daily path of the workplace, allowing employees to work from home. In remote locations, it would reduce costs and improve productivity for employers and employees. The impacts would result in reduced employee spending, office maintenance and cleaning, increased employee retention, increased productivity and new job opportunities;
- Intelligent transportation solutions improve traffic flows and reduce fuel consumption;
- Intelligent power grids more efficiently connect renewable resources, improve system reliability, and consumers are charged based on the efficiency of the operation;
- Through intelligent medicine, doctors and hospitals can receive and organize data from connected medical devices, including wearable and health monitors installed in patients' homes. By receiving the data in real-time, medical professionals thus obtain more complete information of their patients, improving care through more effective diagnoses and treatments;
- Machine monitoring sensors diagnose and anticipate pending maintenance problems and lack of stock.

IoT encompass every aspect of our daily lives, because it literally enables billions of things to be connected anytime, anywhere, to anything or any person. Its applications are many, such as smart houses, connected cars, energy systems, agriculture, transport, health, etc. A single technology cannot effectively meet all the needs of IoT's many applications. Therefore, although some objects use wired connections like Ethernet, Wireless communication technologies play a crucial role in enabling IoT connectivity. According to Kranz (2016), an ideal IoT communication network will be a mixture between the two types, Wired and Wireless. Several technologies can be used in IoT, respectively:

- Wi-Fi – a wireless local area network (WLAN) that transmits via standard IEEE 802.11 radio waves, with a maximum range of 50 meters and a connection speed of 2.4GHz or 5GHz ultra-frequency. This technology is appropriate for transferring large amounts of data between devices. However, this requires a lot of power to operate, while many IoT devices require a much lower data transfer rate than that used by Wi-Fi. This means the batteries of the devices have to be changed on a regular basis;
- Bluetooth – suitable for short-range communications. It transmits data at a bandwidth between 2.4 and 2.485GHz. It operates at distances shorter than Wi-Fi and requires less power to operate. Smart Bluetooth is an important protocol for IoT, because it offers a range similar to Bluetooth but designed for significantly reduced power consumption. However, Smart Bluetooth is not really designed for file transfer and is best suited for small blocks of data;
- Zigbee – enables devices with low operating power, low data rate and low cost of implementation to send data on the network, with each device capable of retransmitting the data towards its intended destination. Its main virtue is its low price and low power consumption;
- Z-Wave – technology, primarily designed for home automation (e.g., products such lamps, sensors, among others). Optimized for reliable, low-latency communication of small data packets with transfer rates between 100kbit / s, it operates in the sub-1GHz band, not interfering with 2.4GHz bandwidth, such as Bluetooth or Z-Wave;
- RFID – technologies that use the radio frequency for data capture. There are several methods of identification, and the most used is to store a serial number that identifies the information in a microchip. Such technology allows automatic capture of data, for identification of objects with electronic devices, known as electronic tags, tags or RF tags, which emit radiofrequency signals to readers who collect this information. This technology can have several applications, such as: security and access control, traffic control of vehicles, personal identification, animal screening, identification of objects, etc;
- NFC – technology that allows data transfer in short distance wireless communication. The NFC has emerged from RFID and, consequently, many of the benefits observed in the previous point are shared by both technologies. Like in RFID, the communication is done in a simple and intuitive way, just by bringing two devices together, or the device and a passive tag, at a short distance. The speed of the NFC throughput is 424 kbits and operates at the frequency of 13.56 MHz.

The existence of a large number of different technologies makes the role of standards more relevant since they provide a way of solving a problem by ensuring the compatibility between different devices. Open standards perform a crucial role in enabling interoperability (Almeida et al., 2010). IoT involves the connection between devices that in most cases were never thought to be connected. It also involves managing those devices and developing applications to do things together that they would never do alone. Consequently, IoT service providers have been advancing with the development of standards by creating alliances for this purpose. These efforts (e.g., AllSeen, Open Interconnect Consortium, Industrial Internet Consortium, etc.) have been developed in key areas of IoT, such as connectivity, interoperability, privacy and security (Naito, 2017; Sethi & Sarangi, 2017).

Security and Data Protection

One of the most demanding challenges for IoT is how data security and the consumers themselves will be guaranteed. Like it happens with smart metering equipment and increasingly autonomous cars, there will be a vast amount of data providing information on the personal use of devices that, if unsafe, could pave the way for privacy breaches. According to Qin et al. (2016), this is a challenge because the high volume of information generated by IoT is essential to bring better services and communities to consumers. Additionally, trust is a key element in the adoption of IoT services. AlHogail (2018) states that it is vital that consumers interact with interconnected IoT devices and systems safely, reliably and intuitively.

The IoT environment is commonly formed by a network of devices connected with sensors. These devices are responsible to transmit the gathered information and specific events to a server. This transmission is made through fixed or mobile communication. Privacy should then be protected at the device level, while communicating with the server, on the server data store, and on processing (Maple, 2017; Yang et al., 2017). In the first case, at the device level, sensitive information can be stolen in the case of manipulation of the hardware or software of the device itself. During communication with the server, the most commonly used approach is encryption. Although it is the most widely used, it may not be the safest, since encryption usually stores data in packets that leave traces, like its sequence number, etc. In relation to the privacy in the storage that is done in the server, it must be filtered of, storing the minimum of possible information, or only what the consumer consents (Liu et al., 2017). Finally, the supplier of each device may use the information collected from these same devices for a variety of purposes, including: analysis or marketing. The user must therefore be able to know what use is given to his data, and whether or not to consent to it being used for a purpose other than the initial and consented (Poudel, 2016).

The challenges of privacy and data protection in IoT can be grouped into five dimensions (Ziegeldorf et al., 2014; Zhou et al., 2018):

- Lack of control and asymmetry of information – the interaction between objects that communicate automatically, and between objects and back-end systems will result in the generation of data streams that can hardly be controlled with the traditional tools used to ensure the proper protection of the interests and rights of the data subjects. This issue of lack of control also concerns areas such as cloud computing or big data, and is even more challenging when it is thought that different emerging technologies can be used in combination;
- Perception of user consent – in many cases, the user may not be aware of the processing of data by certain devices. The possibility of rejecting certain services is not a viable alternative in IoT, and the classic mechanisms used to obtain consent are difficult to apply. Therefore, new ways of obtaining user consent for connected devices should be considered by their manufacturers;
- Redefinition of original data processing – the increased amount of data generated by IoT in combination with modern data analysis and cross-matching techniques may give rise to secondary uses of the same data, whether or not related to the processing purpose initially assigned to the devices;
- Identification of patterns and relationships – although each device generates data streams in isolation, its collection and subsequent analysis can easily reveal individual patterns, behavior, preferences and habits;
- Limitations of user anonymity – the full development of IoT's capabilities can put pressure on the current possibilities of anonymous use of services and limit the possibility of uses to remaining anonymous.

FOCUS OF THE ARTICLE

The article has three main goals: (i) identify the main privacy risks that IoT devices can expose; (ii) analyze the main privacy and security barriers in IoT devices; and (iii) propose countermeasures that can be adopted by companies and users to increase the security of IoT.

This study uses a qualitative methodology by conducting three case studies with IoT service providers. Qualitative research essentially privileges the understanding of problems from the perspective of research subjects. According to Creswell & Poth (2017), the qualitative approach allows us to describe an in-depth phenomenon through the capture and understanding of individuals' perspectives and points of view on a given subject. The main objective of this approach is not to provide generalizations, but to particularize and understand subjects and phenomena in their complexity and uniqueness (Queirós et al., 2017). In this study, the concrete description of the experiences and representations of the individuals leading to a contextual understanding of the phenomena was preferred in opposition to the universal theory and the explanation of the phenomena in a linear causality.

The case study method has been increasingly used in the social sciences, economics and engineering as a procedure for analyzing reality (Yin, 2017). Stake (2005) and Yin (2017) report case study is a methodological approach that allows the researcher to analyze with intensity and depth several aspects of a phenomenon, a problem, or a real situation. Additionally, Gomm et al. (2014) advocate that case study is an empirical research strategy especially useful for phenomena whose frontier between the phenomenon and context are not absolutely obvious. In this context, the collection of information on the main privacy risks and security barriers with the IoT service providers reveals adequate since it is these companies that better know the reality and the innovation of the sector. Consequently, they are also the ones who can best propose countermeasures that can be adopted by companies and users to increase the security of IoT.

The adopted methodology to conduct this study is depicted in Figure 1. It is composed of four sequential stages: (i) preliminary stage; (ii) fieldwork stage; (iii) analysis stage; and (iv) conclusion stage. In the preliminary stage, the concept of IoT is defined and explored in its multiple dimensions. Next, this study analyzes the communication technologies that allow enhancing the use of IoT in several environments such as smart homes, smart cities or wearables and portables. After that, one of the most troubling challenges of IoT is explored, which is how the security of data and its users can be guaranteed. In the fieldwork stage, case studies are carried out with companies that offer IoT products and services in the international market. Afterwards, the analysis stage emerges, which is a crucial point in the methodology. In this phase an individual analysis of the results of each interview is carried out, followed by a comparative analysis of the case studies using a cross-case syntheses, which intends to identify common and individual privacy risks that IoT devices can expose and also explore its main privacy and security barriers, and finally, the explorative data analysis seeks to identify measures that companies and users can implement to increase the security of IoT. Finally, future research directions are discussed, and the main conclusions of this study are listed.

In the process of designing the case studies as suggested by Hancock & Algozzine (2016) the following validity tests were considered: (i) construct validity; (ii) internal validity; (iii) external validity; and (iv) reliability. For that, multiple sources of evidence with an established chain of events were adopted. Additionally, this study used pattern matching to increase internal validity and a replication logic among the multiple case studies to increase the external validity. It is also relevant to emphasize the adoption of a case study protocol proposed by Yin (2017), which composed of five sequential phases:

Figure 1 – Phases of the research methodology

1. Case study design – involved three companies that develop IoT solutions for international markets. Semi-structured interviews were considered and organized into three dimensions as presented in Table 1;
2. Data collection preparation – semi-structured interviews were conducted within these companies. According to Jamshed (2014), semi-structured interviews allow respondents to express freely their point of view and simultaneously encourage two-way communication with the interviewer. Additionally, they provide a reliable method for analyzing comparatively qualitative data (Leung, 2015). The interviews were carried out with the technical managers for the development of IoT solutions in the facilities of these companies;
3. Collecting evidence – informal notes according to each response given by the interviewee were collected by the interviewer. Finally, a preliminary draft of the case study report was created and validated by the respondents;
4. Analyzing evidence – theoretical propositions were used to compare collected evidence on the case studies versus the information collected in the background of this study. Furthermore, cross-case syntheses were adopted to identity common evidences among case studies;
5. Reporting case studies – a final report gathering all the information collected from case studies was compiled.

The profile of the companies selected for the case studies is depicted in Table 2. Although all three companies work in the IoT field, the area of intervention is quite distinct due essentially to the wide range of available technologies and very diverse applications field of IoT, such as games, virtual reality, cultural events, health, smart homes, smart cities, wearables or smart retail.

SOLUTIONS AND RECOMMENDATIONS

Contextual

All interviewed companies are focused in providing end-to-end solutions, offering the best usability and suitability to business needs. They typically develop and integrate Web, mobile and interactive interfaces always with the aim of delivering concrete information, with little or no user interaction. IoT is

Table 1. Interview questions

Dimension	Questions
Contextual	Q1. What is the main business field of your company? Is it only dedicated for developing IoT solutions?
	Q2. What were the main challenges faced by IoT companies during the past years?
Diagnostic	Q3. What are the main technologies adopted in the development of IoT solutions?
	Q4. What are the main privacy risks that IoT devices can expose?
	Q5. What are the main privacy and security barriers to the adoption of IoT solutions?
Strategic	Q6. What are the main countermeasures that companies and users can adopt to increase the security of IoT?
	Q7. What differentiate your companies from your main competitors?

Table 2. Profile of companies

iD	Established date	Description
CS1	2008	Company that develops creative, customized and interactive software for Events, Brand Activators and Museums, Holograms, Virtual Reality, Video-mapping, 4D Rooms, 360° Immersive Rooms, Augmented Reality and Interactive Games.
CS2	2012	National and international consulting company in the telecommunications field. Responsible for the conception, development, implementation and management of national and international technological projects. The company also offers training in the telecommunications field.
CS3	2006	Company that provides engineering solutions with integrated intervention in fixed and mobile networks, new generation networks, systems and all types of technological infrastructures.

one of the actions areas of those companies, as many customers depend on enterprise systems that need rich, near real-time, accurate data, as well as optimized process management. However, IoT is usually a component in an IT wider infrastructure.

Changing the human mentality emerges as the main challenge faced by IoT companies during the past years. CS2 refers that at this level in a first phase the company experienced difficulties due to the lack of knowledge on the part of customers about IoT and, in a second phase, it was consequently necessary to evangelize the end users as well. Other challenges more related to technological issues emerge, such as:

- Integration – a very high number of connected devices makes the integration and concurrent data exchange complex. Additionally, IoT sensors use new and novel communication protocols, which turn difficult to integrate with older devices;
- Security – small devices typically have limited CPU power. Consequently, there is little processing power for implementing security mechanisms. Furthermore, it is important to note that IoT needs to offer mechanisms for identity management and encryption key management;
- Privacy – IoT devices generate a vast amount of critical data that creates potential manipulation risks, for example in terms of identity theft, data falsification, external network manipulation or cybercrime;
- Connectivity – it becomes difficult to ensure that all IoT devices and the system is up and running. Additionally, sometimes data reading can be incorrect due to hardware, atmospheric or environmental issues.

Diagnostic

One of IoT's greatest challenges is the integration of a large number of very diverse technologies. Technologies in this area include the network for Personal Area Network (PAN), Local Area Network (LAN), Metropolitan Area Network (MAN) and Wide Area Network (WAN), such as RFID, NFC, Bluetooth, Zigbee, WiFi, Winmax or 3G/4G. Other technologies are also typically included in the development of end-to-end applications, such as Java, Python, nodeJS, REST, Elastic Search (ELK), Docker¹ or Kubernetes².

IoT devices operate in hostile environments and a potential attack surface in IoT platforms is much larger than in other traditional systems. Therefore, it requires end-to-end security, from sensors and actuators to management interfaces. Moreover, protocols like Message Queuing Telemetry Transport (MQTT) were not designed with security in mind. Security is often implemented adding a TLS layer, but that's not acceptable for lower end CPU devices without dedicated encryption engines. Consequently, potential privacy risks are spread: sensor data sniffing is a risk, but attacks on backend or analytics subsystems can represent the highest risk, as they can expose the most important and secret business related information. Other potential risk referred by CS3 is that weak configurations tend to persist along the time which creates potential hidden risks that can be exploited in a cyber attack. In this sense, IoT security must be essentially preventive and not corrective. This is particularly relevant in high sensitive industries like healthcare, where the primary goal is to ensure that security network is resilient to prevent data leaks from malicious attacks (Razzaq et al., 2017).

Sense of insecurity can be seen as the main privacy and security barrier to the adoption of IoT solutions. In fact, as mentioned by CS1 the first generation platforms were insecure by design, and that led to improper situations. These notices were quickly shared by several users on newspapers and social networks, which generated a feeling of insecurity that is difficult to combat. Additionally, users may not want there to be an increase in information that is shared. It is therefore essential that there is a right balanced between the desire for new services that make life easier for people and companies, but in which critical and personal data are properly secured.

Strategic

There are good practices and countermeasures that companies and users can adopt to increase the security of IoT. Firstly, it shouldn't be used in production environments anything that wasn't carefully analyzed previously. It is fundamental to consider that security audit tools are essential in any IT infrastructure, but IoT systems require additional deep data traffic analysis, in order to identify improper data streams. CS1 recommends not using arbitrary libraries if the IoT solution is developed internally. Other identified good practice referred by CS3 is the adoption of a risk-driven approach. The idea is to create a risk matrix to all IoT devices and then apply security controls mechanisms suitable to the level of risk involved. The same company also states the importance to automate security when possible. This approach will contribute to have a better data monitoring process.

The differentiation of companies operating in IoT is made based on the creation of integrated solutions. Because the scope of IoT is very broad, there is a wide range of differentiation opportunities. Companies should explore the integration of IoT and other enterprise systems, like Business Process Management (BPM), production management, document dematerialization, Geographic Information System (GIS), and mobile platforms to optimize benefits to the customer.

Table 3. Comparative analysis

Question	CS1	CS2	CS3
Q1	- Development of Web and mobile applications - IoT is used in the scope of those projects	- Provide end-to-end solutions - IoT is one of the action areas	- Provides engineering solutions with focus in the IoT segment
Q2	- Lacks of customers' knowledge - Evangelize end-users	- Human mentality, integration and security	- Connectivity, security, privacy, compatibility and Big Data
Q3	- Only integrate solutions	- Considering not only technologies but programming languages and integration products	- There is a wide and high volume of different technologies, such as REST, Python, Java, Angular, or Kubernetes
Q4	- The great risk is due to an increase in the volume of information	- IoT requires end to end security, from sensors and actuators to management interfaces	- IoT handles data that can be used by mining and machine learning algorithms to obtain very sensitive personal information
Q5	- Users may not want there to be an increase in information that is shared	- Sense of insecurity is a barrier, as first generation platforms were unsecure by design, and that led to improper situations - On the technical side, the lack of embedded crypto engines	- Related with privacy and data leaks
Q6	- Identify critical information - Not used arbitrary libraries in internal developed solutions	- Don't use in production environments anything that wasn't carefully analyzed previously - Use security audit tools - Always apply the generic best practices for IT systems	- Adopt a risk-driven approach - Consider the entire IoT ecosystem - Wherever possible, automate security
Q7	- Working with all kinds of technologies	- Don't be focused on the IoT itself, but act to explore the integration of IoT systems	- Create integrated solutions

Comparative Analysis

Finally, a comparative analysis of the outcomes of each of the interviews conducted in each case study was carried out. The information in Table 3 is organized by the established questions, in which CS1, CS2, and CS3 represent each case study. For each case study, the key points and their main differences are highlighted.

FUTURE RESEARCH DIRECTIONS

IoT adoption is already a reality in society, but there is still a lot of resistance, especially in terms of security and privacy. Many companies are not yet properly prepared for the challenges of IoT, since a change in the culture of these organizations is necessary.

Lee et al. (2017) and Liu et al. (2018) synthesize the main research directions into four domains:

- Networking – research is needed into innovative dynamic routing approaches that prioritize content according to its criticality and importance for increasing networking performance. At this level, research projects in virtualization technology, self-configuration, and self-organization networks stand out;
- Standardization – the proliferation of technologies creates difficulties in interoperability between devices. At this level it is necessary to make efforts in IoT standardization and semantic interoperability;
- Energy consumption – due to the small size of IoT devices it is essential to offer efficient battery management mechanisms. Emerging research in the field of micro battery technologies stands out in this respect;
- Security and privacy – it becomes necessary to increase the awareness of the security and privacy offered by IoT in multiple dimensions, such as integrity, non-repudiation, authenticity, confidentiality, privacy and availability. In this sense, research has emerged in the area of security for cloud computing, security for semantic web and crypto engines that could be embedded into IoT devices.

IoT does not exist without artificial intelligence (AI) and, consequently, this is an extremely relevant research topic. Emerging areas of research in this field include machine learning, autonomous and incremental deep learning, and soft artificial intelligence (Song et al., 2018; Milton et al., 2018; Chatterjee, 2018). The AI will necessarily play a key role in obtaining and analyzing results automatically, thus seeking to integrate knowledge from multiple sources using distributed big data models. The security of this process and the privacy in the treatment of this data are one of the most relevant and challenging topics.

Social Internet of Things (SIoT) is other emergent research field. SIoT represents the convergence of the “Internet of Things” and the “Social Networks” worlds (Mendhurwar & Mishra, 2018). SIoT establishes new type of relationships between objects, such as social object relationship, ownership object relationship, and co-location object relationship and co-work object relationship. Future research is needed in terms of securing the SIoT and trustworthiness management. Other relevant topic is the intelligent data process and use the knowledge produced by IoT devices in big data analytics (Ahmed et al., 2017). Research is being developed in data mining, machine learning, predictive analytics and real-time big data.

CONCLUSION

IoT is a new technological paradigm that aims to transform the way we live and work. IoT offers great opportunities to create new custom products and services, but also countless security and privacy challenges. With IoT devices and connected users on the rise, there will also be an enormous amount of data about how each individual uses a given device or application. This information leaves traces of citizens’ everyday behaviors, providing sensitive information that is intended to be private and anonymous.

Several challenges have been felt by IoT companies mainly in the field of human mentality, security, privacy, connectivity and compatibility. The biggest challenge has been to encourage customers to believe in the success of the IoT market and to evangelize end users. It is also worth highlighting the difficulties experienced by companies in working with such a large number of technologies that pose difficulties of interoperability and compatibility.

Companies can implement several countermeasures to increase the security of IoT. The adoption of security tools is essential in a IoT infrastructure. Therefore, companies must apply generic best practices for IT systems, starting from careful user management and security patches installation. Security mechanisms must consider the entire IoT ecosystem and not single devices. The adoption of a risk-driven approach is another relevant strategy that allows companies to apply security controls appropriate to the level of risk involved. This strategy is particularly relevant in complex IoT environments composed by several IoT devices. Finally, it is important to automate security wherever possible. This approach will turn possible to establish preventive security mechanisms that can contribute to increased automation in data monitoring.

KEY TERMS AND DEFINITIONS

Local Area Network (LAN): Computer network covering a small local area, like a home, office, or small group of buildings such as a home, office, or college.

Metropolitan Area Network (MAN): A network that connects two or more local area networks together but does not extend beyond the boundaries of the immediate town, city, or metropolitan area.

Personal Area Network (PAN): A network typically involving small devices organized around an individual person.

Privacy: Ensuring privacy involves citizens having control over existing information about themselves and exercising this control in a consistent manner with their personal interests and values.

Security: A set of measures taken to protect oneself from any acts of violence, such as attacks, robberies, espionage, sabotage, etc.

Wi-Fi: Abbreviation of wireless fidelity, standard technology for wireless access to local networks. This technology allows electronic devices to be connected to a wireless local area network (WLAN) and Internet using radio waves.

Wide Area Network (WAN): A group of computer networks connected together over a large geographical distance crossing metropolitan, regional, or national boundaries.

Winmax: Technology that allows the expansion of the internet signal at higher speeds over long distances.

Zigbee: Protocol that is employed for PANs and is based on the IEEE 802.15 standard. Even though they are low-powered, Zigbee devices can transmit data over long distances by passing data through intermediate devices to reach more distant ones, creating a mesh network.

INTRODUCTION

One significant benefit of the development of information technology is its positive impact on the health sector. Over the last years, the use of electronic patient records has illustrated rapid expansion. The advancements in health information technology, the limited potential of the traditional processes and the need for flexible access to health information, have promoted new paradigms and as a result, personal health record (PHR) systems, empowering both patients and healthcare providers, present a constantly evolving area for research, development, and implementation (Genitsaridi, Kondylakis, Koumakis, Marias, & Tsiknakis, 2015). The technological challenges intertwined with the increasing adoption of such tools and platforms are optimally addressed with the rise of Cloud Computing (Martens & Teuteberg, 2012) which is formally defined as “*a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources that can be rapidly provisioned and released with minimal management effort or service provider interaction*” (Mell & Grance, 2011). Promising coherence and economies of scale through the ability of robust sharing of computational resources, Cloud Computing has been a continuously evolving sector over the last decades (Guzek, Bouvry, & Talbi, 2015).

Furthermore, the availability of large medical datasets for secondary purposes such as research has become a powerful tool for producing knowledge and information, leading the medical and health care sector to a new, more personalized level. Large-scale biomedical databases are created and continuously enriched for research purposes while providing the right tools for handling and analyzing their content (Dankar & Al Ali, 2015). Researchers using personalized patient medical data have the ability to present valid and reliable data, to reuse existing data, and to compare the results of their study with similar ones based on the same database (Emam, 2013).

DOI: 10.4018/978-1-5225-9715-5.ch052

As the type of data shifts toward electronic records and large datasets are made accessible via distributed networks and the world wide web, hospitals, and other health providers increasingly suffer from data breaches whose nature likewise shifts toward electronic means, such as hacking (Spitzer, 2018). A data breach is “*an impermissible use or disclosure that compromises the security or privacy of the protected health information and is commonly caused by a malicious or criminal attack, system glitch, or human error*” (Bai, Jiang, & Flasher, 2017). Breaches can be conducted by a variety of ways, including credential-stealing malware, an insider who either purposefully or accidentally discloses patient data, or lost laptops and smart devices (Center for Internet Security, 2018).

Healthcare industry is highly targeted by cybercriminal organizations and individual hackers, as, according to research, an individual’s medical data, are 20 to 50 times more valuable to cybercriminals and black market than other types of targeted information, e.g., personal financial data, credit card details, social security numbers, etc. (Center for Internet Security, 2018). Therefore, cybercriminals have higher incentives to target databases with medical content in order to sell or exploit the sensitive information for their own personal gain (Center for Internet Security, 2018). In this context, it is not a coincidence that the biggest recent data breaches have seized health care records as the prize.

Access to highly sensitive medical information which is exposed through data breaches, gives cybercriminals the opportunity to commit identity theft, medical fraud, extortion, and the ability to illegally obtain controlled substances (Kruse, Frederick, Jacobson, & Kyle, 2017). More specifically, patient records can be used for various types of financial gain, including (Boden, 2018):

- sale on the Dark Web
- fraud commitment (tax, insurance frauds)
- extortion of people whose disclosure of illness could provoke public relationships problems and difficulties in their working environment
- targeted phishing campaigns against individuals whose records were leaked

In the recent years there is an uptick in attacks against health care systems due to a variety of factors, including low organizational vigilance, inadequate and poorly trained staffing, insufficient technology investment and funding for information technology security, all these combined with the potential value of healthcare data as compared with other industries (Gordon, Fairhall, & Landman, 2017).

CURRENT TRENDS

In the past years, the growth of healthcare data breaches in both size and frequency was remarkable, with the largest breaches having an impact on millions of people (Chideya, 2015). In the years 2016-2017, approximately 90 percent of healthcare providers were faced with data breaches and cyber-attacks were up 125 percent since 2010 (Kruse et al., 2017). Currently, in the U.S., the number of individuals affected is estimated to be more than half of the total population.

A data breach outside of the USA that is worth mentioning is the Singapore Health cyberattack. The personal particulars of almost 1.5 million patients, including that of the country’s Prime Minister, were stolen from the database. The data include both demographic and medication records (Singhealth et al., 2019). On the other hand, National Health Service (NHS) was on the top of the list for serious data breaches in 2014. The percent of severe data breaches that were reported to the Information Commis-

sioner's Office was highly increased, while most of the incidents were related with human error and deficient data handling and not with technical reasons (Gilbert, Goldstein, & Hemingway, 2015).

Following the development of a market for stolen data and related hacking skills, hospitals and other healthcare providers have become popular targets for hackers and cybercriminals. As an example, in June 2016 a hacker offered for sale in "Real Deal" dark web marketplace more than 60.000 medical records from three different systems, one of which was an entire electronic health record, including screenshots. In the same month, cyber-attacks disclosed more than 11 million healthcare records (Chideya, 2015; Koczkodaj, Mazurek, Strzałka, Wolny-Dominiak, & Woodbury-Smith, 2018).

Table 1 presents the top 10 biggest healthcare data breaches, according to the U.S. Department of Health and Human Services Office for Civil Rights. The breaches are illustrated in descending order, regarding the number of individuals affected.

VULNERABILITIES - ATTACK METHODS

Social Engineering

Regardless of how strongly the security is maintained on the systems' level, human intervention always should be considered as the weakest link in the security chain. Social engineering is a set of techniques used by cybercriminals, that allows the access to buildings, systems or data by exploiting human psychology, or, defined from a different angle, *"the science of using social interaction as a means to persuade an individual or an organization to comply with a specific request from an attacker where either the social interaction, the persuasion or the request involves a computer-related entity"* (Junger, Montoya, & Overink, 2017).

Used as a technique to penetrate any type of system, exploiting humans related to it rather than vulnerabilities in the system itself, Social Engineering Attacks are rather powerful because they operate on a level such that there is no hardware or software that can prevent or even help defend against them (Koyun & Al Janabi, 2017). Although the nature of this attack is not considered as technical, social engineering methods are widely used by cybercriminals. These tactics, which are based on the manipulation of people's psychology by exploiting their possible lack of awareness and the tendency to trust easily are often far more effective and faster than software hacking. (Criddle, 2017). So, social engineers may use a combination of collected data regarding their victims in order to make them believe that they are authorized users, for example, IT employees, and reveal to them confidential information such as passwords. It is a fact that most people want to be kind and courteous and are trained to be compliant, especially in a work environment. If a potential intruder calls up as an angry executive and claims that he wants to know, for example, why nobody has taken care of a specific routing number and account number which were supposed to be changed, with a sense of urgency to it, employees tend to obey immediately.

A social engineering attack can be accomplished by a variety of ways; phone, web, email, USB drives to name such a few. Most common social engineering categories include:

- **Phishing** is the most widely known social engineering attack and is normally executed via emails and social media. Victims of such an attack usually receive emails or text messages from an entity that either they trust or seems to be legitimate, for example, a friend, their bank or university. These messages often contain malicious links that redirect recipients to websites which can either trick them into revealing sensitive information or automatically download malware which can

encrypt useful files of the system (ransomware attack). The targeted phishing attacks are usually the most successful because criminals collect personal information from customers and use it in order to create more convincing emails. For example, criminals can imitate effectively emails from online shops just by mentioning the customer's name and the products they purchased. The more information an attacker has collected about the target, the better he can imitate emails from trusted entities. According to an experiment about phishing attacks, using data from social media, individuals are 4.5 times more likely to get deceived from a message sent from a contact they trust than from standard phishing attacks. It is important to be mentioned, that at the Corps of Cadets at West Point 512 students received a phishing email which concerned a problem with their grades. The vast percentage of 80% opened the link embedded in the email. (Junger et al., 2017).

The majority of criminals who perform phishing attacks aim to gain access to personal information, such as age, names, addresses, credit card details, social security numbers, and health records. Phishing methods exploit fear in order to deceive users and make them react thoughtlessly. For instance, criminals can send victims via email that the password for a service will be expired and they should update it within 24 hours, otherwise they will lose their account.

- **Pretexting** is another social engineering category, where attackers try to divulge victim into trusting them and give them access to either sensitive or non-sensitive personal information, by generating an effective pretext, a scenario that seems plausible or a story that cannot be doubted. Pretexting attacks aim to build a notional trust relationship with the target, in contrast to phishing tactics, which take advantage of emotions such as fear in order to manipulate individuals. (Bisson, 2015).
- **Baiting attack** is one of the simplest social engineering methods since, usually, all that it involves is an external storage device. This kind of attack exploits people's natural curiosity and its main difference from the other social engineering methods is that hackers use to tempt their victims by offering them an item or a service. For example, targets may be offered services like free movies or music, if they submit their login credentials to a given website in return. (Bisson, 2015).

Concerning baiting attacks through physical media, criminals often leave intentionally a device that contains malicious software in a public place, where potential victims can easily find and use it. This place could be a parking lot, a park, the corridors of a company, or even a pavement. If a number of individuals find such a device and plug it into their computers, curious to discover what will happen, baiting attack will achieve its purpose. In 2006, the founder of Secure Network Technologies Inc conducted an experiment in order to evaluate the security level of a client. His team scattered a significant number of malware-infected USB devices around the company's parking lot. Many of the company's employees plugged the devices into their computers and, as a result, they unintentionally activated a keylogger which exposed their login information.

- **Quid pro Quo attacks** are similar to baiting attacks, as they deceive people into believing that they will receive a service or a good if they provide information. In contrast to baiting, which usually relates to an item, quid pro quo attacks frequently use provision of services in order to attract victims. One typical instance of quid pro quo attack includes criminals who call targets and pretend to be IT experts who will help victims fix their software problems if, for example, they

Table 2. *Top Web Application Vulnerabilities. Selected from (“Top 10-2017 Details About Risk Factors - OWASP,” 2017)*

Risk	Exploitability	Prevalence	Detectability	Impact
Injection	Easy	Common	Easy	Severe
Broken Authentication	Easy	Common	Average	Severe
Sensitive Data Exposure	Average	Widespread	Average	Severe
Broken Access Control	Average	Common	Average	Severe
Security Misconfiguration	Easy	Widespread	Easy	Moderate
Cross-Site Scripting (XSS)	Easy	Widespread	Easy	Moderate
Vulnerable Components	Average	Widespread	Average	Moderate
Insufficient Logging Monitoring	Average	Widespread	Difficult	Moderate

disable their antivirus program and install some updates on their computer, which is, in fact, malicious software. (Bisson, 2015).

- In **tailgating attacks**, fraudsters try to gain access to a restricted area, for example, a company, by exploiting an authorized person such as an employee. Frequently, criminals pretend to be delivery drivers or couriers and ask from the employees to hold the door for them. Tailgating is not effective in work environments such as large companies where all individuals who require to enter the building are obliged to use their personal card. (Bisson, 2015)

Web Application Security Risks

As an increasing number of patient data are made available to both patients and health professionals through web application interfaces, the “innate” security, which depends on careful and responsible application development processes, becomes of crucial importance. Vulnerabilities that derive from developers’ sloppiness or lack of knowledge present a favorite hacking target, and they are, more often than not, easier targets to exploit compared to system level processes, which are typically hardened by default. There are numerous known vulnerabilities on that level. One of the most comprehensive lists, compiled by Common Weakness Enumeration (CWE), a “community-developed list of common software security weaknesses,” contains no less than 716 items (“CWE - CWE List Version 3.1,” 2017).

Open Web Application Security Project (OWASP) is an international organization “dedicated to enabling organizations to conceive, develop, acquire, operate, and maintain applications that can be trusted.” As part of their foundation statement they “advocate approaching application security as a people, process, and technology problem because the most effective approaches to application security include improvements in all of these areas” (“About The Open Web Application Security Project - OWASP,” 2018). Among other activities, OWASP conducts worldwide research about the most prevalent web application vulnerabilities that allow successful attacks to internet users’ privacy and security. Table 2 presents a selection of OWASP’s top 10 vulnerability list, adapted to the specific nature of HealthCare systems, along with threat assessment classifications.

More specifically:

- **Injection:** Injection flaws occur when, under any circumstance, the user provided command or query data is allowed to be executed on the interpreter level, thus giving an attacker the opportunity to perform unintended commands without proper authorization. Given that this type of vulnerability is very common, particularly in legacy code, injection attacks are on the rise and can sometimes lead to complete host takeover. In the most typical scenario, a hacker executes a SQL query from the Internet to perform an operation on the recipient's database and transfer data back to themselves (Harries & Yellowlees, 2013).
- **Sensitive Data Exposure:** Data Attackers can steal or modify weakly protected data when there is no extra protection such as adequate encryption both when stored (at rest) and during the communication of the server with the user's client, e.g., internet browser (in transit). Often there is no encryption used whatsoever. However, even when crypto is employed, vulnerabilities could emerge from the use of weak and/or obsolete algorithms, as well as wrongly implemented key generation, exchange, and cipher usage.
- **Broken Authentication:** If application procedures related to authentication and session management are not implemented correctly, which is often the case, this allows attackers to assume other users' identities temporarily or permanently, making use of compromised passwords, keys, or session tokens. Common attack methods used are credential stuffing (as there are publicly available databases with millions of valid credential combinations as well as default administration account lists), dictionary/rainbow attacks, and automated brute force. Also, poorly implemented session management is a favorite target, as it lies in the center of authentication and access control mechanisms and exists in all stateful applications.
- **Broken Access Control:** Such flaws occur when an attacker can gain unauthorized access to functionality and/or data, due to poorly enforced restrictions on what authenticated users can do. Failure to implement effective access control, that is to enforce policies to prevent users from acting outside of their assigned permissions, can allow perpetrators to access administrative/privileged functions or to act on behalf of other users, increasing the probability of data disclosure, modification or destruction.
- **Security Misconfiguration:** This is one of the most commonly seen issues and can be observed at all levels of the application stack (network, platform, web/application/database server, virtual machines, containers, and storage). Lack of diligence and/or knowledge can result to a number of insecure configurations (default accounts with unchanged credentials, administrative or development access routes –e.g., ports, services- forgotten active and unprotected, etc.), allowing the attackers to relatively easily access sensitive functionality and data.
- **Cross-Site Scripting (XSS):** XSS flaws occur whenever malicious HTML and/or Javascript code included in user input is not properly handled (validated and/or escaped) and is allowed to be part of the web page output or to be executed in the victim's internet browser. This can happen during the same session (Reflected XSS), at a later time by another user (Stored XSS) or by exploiting dynamically structured web applications (DOM XSS). Executing hostile code via XSS in the user's browser can result in user session hijacking, defacing, or redirection the user to attacker-controlled sites.
- **Using Components with Known Vulnerabilities:** More often than not, development teams working with component-rich applications fail to keep track of which components they use, as well as keeping them updated and properly patched. Many of the large recorded breaches have

relied on exploiting known vulnerabilities in third-party components, as, in most of the cases, they share the same execution privileges with the main application.

- **Insufficient Logging/Monitoring:** This flaw is the foundation of nearly every recorded major incident as it provides attackers with valuable time to achieve their goals before being detected. Data from 2016 suggest that the detection and identification of a breach took, on average, more than 190 days. Given the privilege of time, attackers can dig deeper, pivot to adjacent systems, and introduce new vulnerabilities. On the contrary, timely response to a security incident can, most of the times, reduce dramatically the final impact.

Database Anonymity Issues

Patient privacy must be one of the main considerations when attempting to distribute and share medical data for secondary purposes. Research has shown that datasets that may seem completely anonymized are prone to specific types of attacks that can result in one or more physical persons' identification. The identifiers through which an individual's identity may be revealed can be divided into two categories (El Emam, Rodgers, & Malin, 2015):

- **Direct Identifiers:** they include data allowing the immediate identification of the holder, such as the name, the identity card number, the social security number, etc.
- **Indirect Identifiers or Quasi-Identifiers:** They include characteristics such as age, gender, occupation, residence, etc., which do not directly identify an individual, but their combination may lead to revealing identity and violating personal privacy. Indirect identifiers may also include the sub-category of sensitive attributes, which are not public data and can be harmful or lead to stigmatization when associated with a particular person. Such features include drug and intervention codes, as well as certain diseases (Eze & Peyton, 2015). The attack may involve either the identification or attribute disclosure. During the identification disclosure, the attacker uses the indirect identifiers of an anonymous record to associate them with a particular person. During the attribute disclosure, on the other hand, the perpetrator of the attack can infer some sensitive information about a person even if he/she cannot identify and find which unique record corresponds to him/her. A third and less frequent form of attack is membership disclosure, which is a probabilistic measure of the presence or absence of a person in a data set (Eze & Peyton, 2015).

Improper handling of these identifiers or their combinations can give attackers the opportunity to re-identify parts of the respective datasets, which, most of the times, given their medical research purpose, contain extremely sensitive data.

Attacks That Do Not Disclose Sensitive Data

Although the attacks that aim to the disclosure of personal health information are far more worrisome, cyber-attacks that do not necessarily result in data breaches, can potentially have a significant impact in terms of cost, loss of trust, etc. (Gordon et al., 2017) The most common types of these attacks are:

- **DoS (Denial of Service) Attacks:** Criminals can use a variety of methods in order to harm health care providers. A widely known category of attacks that are used against health care systems is Denial of Service (DoS) attacks which flood systems with a vast amount of network traffic in order to disable them. This kind of attacks in the healthcare sector may be dangerous or even fatal as they may affect operations such as surgical procedures or reporting of lab results by rendering hospital care systems unusable. (Gordon et al., 2017)
- **Ransomware:** Ransomware attacks have as main characteristic the encryption of selected files in an information system, for example, a patient database, and the request of a fee, usually in cryptocurrencies such as Bitcoin, in order to give victims, the key to regaining access to their files. (Gordon et al., 2017) Restricted files are usually highly significant for the smooth operation of hospital procedures, and as a result, hospitals are forced to pay the criminals. Otherwise, there is the possibility of losing vital data. Even if organizations keep daily backups of their files, there is always the risk of losing information if they restore from a backup after a ransomware attack.

The creation of ransomware dates back to 1989 when Dr. Joseph Popp used malware-infected floppy discs which distributed to attendees of the WHO (World Health Organization) conference that focused on AIDS research. Although Dr. Popp ended up in prison, his creation inspired many aspiring cyber attackers. A recent example of a ransomware attack is the WannaCry attack in 2017, which had an impact on NHS. Concerning the ransom fee, most of the times, it seems inferior to the consequences that will provoke a potential data loss to an organization, which may include profit loss and damaged security reputation. However, even payment does not ensure access to encrypted files, as ransomware victims are totally dependent on the attacker's reliability. (Gordon et al., 2017) *'Ransomware exposes and exploits the vulnerabilities of 21st-century information technology (IT) infrastructure'* (Kruse et al., 2017)

Monetization Routes

The main motivation for conducting a major attack to gain access to large datasets of private sensitive information is profit, thus, once the data acquisition is achieved, the next perpetrators' move, predictably, is the effort of monetization. Most of the times, the preferred method includes black market structures that utilize the anonymity and counter-tracking environment provided by dark/deep web and cryptocurrency, which are briefly presented in the subsequent sections.

Deep/Dark Web

What is known as Deep Web, Deep Net, Invisible Web, or Dark Web (Weimann, 2016), is the non-indexed by standard search engines content of the World Wide Web. If the Internet is considered as a multi-tiered structure, only the top tier, i.e., the surface web, can be accessed with the regular search engines that are commonly used (such as Google). The rest, the deepest tiers, which are the essential content of the Deep Web, is a wealth of information. Searching the internet has been compared to *"dragging a net across the surface of the ocean: a great deal may be caught in the net, but there is a wealth of information that is deeper and therefore missed"* (Bergman, 2001). In the early days of the Internet, as the size of information was not immense, it was indexed and accessed in an easier way. However, as its use inflated, conventional search engines are proving insufficient for searching and indexing dynamic pages, whereas they are adequate for static web pages. Dynamic pages can be accessed through specific

and targeted queries and programs, while static pages are linked to other pages on the internet, therefore the name “Invisible” web.

The Deep Web is inaccessible by conventional means, with its contents hidden or often blocked. Although its size can't be measured, it has been estimated (Bergman, 2001) that public information on the Deep Web is currently 400 to 550 times larger than the commonly defined web, although there have been since more moderate estimations (Cox, 2015).

A segment of the Deep Web is the Dark Web that contains information that is considered generally illegal, antisocial and it is possible to access it only through specialized browsers, created for this specific task. Examples of such pages may include illegal paraphilia, leaks on unauthorized information, financial trails on money laundering, frauds, identity thefts, illegal transactions, trafficking, etc. Associated with the Dark Web is the rise of relevant sub-cultures (Bartlett, 2015) such as social media rapists, crypto-anarchists, transhumanists, traffickers, etc. The Dark Web can be visited by all Web users, by software such as Tor, free software for enabling anonymous communication. The name is derived from an acronym for the original software project name “The Onion Router.” Tor directs Internet traffic through a free, worldwide, volunteer overlay network consisting of more than seven thousand relays to conceal a user's location and usage from anyone conducting network surveillance or traffic analysis. Another relevant software is the Invisible Internet Project (I2P), which is an anonymous network layer that allows for censorship-resistant, peer to peer communication (Ali et al., 2016; Astolfi, Kroese, & Van Oorschot, 2015). These anonymous connections are implemented by encryption (end-to-end) of the user's traffic and delivery of the information through a volunteer-run network of roughly 55,000 computers distributed around the world. Given the high number of possible paths the traffic can transit, a third party watching a full connection is unlikely to successfully gather information about the communication. The software that implements this layer is called an “I2P router”, and a computer running I2P is called an “I2P node”. I2P is free and open source and is published under multiple licenses. The overall principle is that whatever tool a visitor uses, one must know where exactly to find the website, by its Uniform Resource Locator. Once inside the Dark Web, communication means include secure email, Web Chatting, or Tor-hosted Personal Messaging (PM).

Cryptocurrency

Cryptocurrencies use decentralized control versus centralized digital currency and the traditional banking system. They are transferred between peers, and they are confirmed in a public ledger with a process that is called mining (Dziembowski, 2015).

More specifically, these public ledgers are storing all confirmed transactions, from the beginning of each cryptocurrency's creation. Information regarding the cryptocurrency's owners is encrypted, as well as the legitimacy of record keeping. When there is a transaction, meaning a transfer of funds between digital wallets, this is submitted to the abovementioned public ledger, while confirmation is pending. In order to provide mathematical proof and a legitimate link between the owner of the wallet and the relevant transaction, an electronic signature is used, which is an encrypted piece of data. Then ‘mining’ confirms the transactions, and they are added to the ledger. The mining process is what essentially gives value to the cryptocurrency and is its proof-of-work system. Cryptocurrency mining, or crypto mining as is otherwise known, is the process of transactions verification, by cryptocurrency miners, who are responsible for ensuring the authenticity of information and updating the blockchain. Cryptominers, compete with each other, in solving complex mathematical problems and the first one to

find the solution, authorizes the transaction, while being rewarded for the service provided by earning small amounts of cryptocurrency.

Bitcoin, described as the currency of the Dark Web, was proposed in 2008 as an alternative and independent currency by S. Nakamoto (Nakamoto, 2008). Currently (Hurlburt, 2017), it is being rapidly replaced by Monero, a private, digital currency that is offering mechanisms that prevent the indirect tracing of those that are conducting transactions (Amsterdam, 2018; Noether, 2016).

COUNTERMEASURES

A countermeasure is a procedure that reduces vulnerability by eliminating or preventing it, by minimizing the harm it can cause, or by discovering and reporting it so that corrective action can be taken. A set of policies concerned with information security management has been developed to manage, according to risk management principles, the countermeasures in order to accomplish a security strategy set up following rules and regulations applicable in the world. Below the various existing protocols of preventing any misuse of healthcare data are described.

Government Regulations

HIPAA (Health Insurance Portability and Accountability Act)

HIPAA (Health Insurance Portability and Accountability Act) is a United States legislation which provides guidelines regarding the security of sensitive medical information and enacted in 1996 by Bill Clinton (HIPAA, 2018)

Before the activation of HIPAA, there were no healthcare security guidelines or requirements with a focus on the protection of personal health data. The existence of such legislation has become vital during the last few years when the number of cyber-attacks targeting healthcare providers, which resulted in health data breaches illustrated a rapid increase.

HIPAA is organized into five (5) separate sections or “Titles” (“HIPAA (Health Insurance Portability and Accountability Act) | whatis.com,” 2017):

- **Title I, “HIPAA Health Insurance Reform.”** This section refers to new employees’ medical insurance coverage. According to this title, employers should allow new employees’ coverage to be uninterrupted regardless of any pre-existing conditions or health problems.
- **Title II, “HIPAA Administrative Simplification.”** When mentioning HIPAA compliance, most people mean adhering to HIPAA Title II. This part of the legislation sets the national standards for processing electronic healthcare transactions. It also requires the implementation of secure electronic access to personal health information, and all healthcare organizations’ activities must be in accordance with privacy rules.
- **Title III, “HIPAA Tax-Related Health Provisions.”** In the presented title, tax-related provisions are concerned.
- **Title IV, “Application and Enforcement of Group Health Plan Requirements.”** This section additionally provides information concerning insurance reform and provisions for individuals who request subsection to continuous insurance coverage.

- **Title V, “Revenue Offsets.”** The presented title provides regulations concerning company-owned life insurance and the behaviour towards individuals who lose their U.S. citizenship for income tax purposes.

All HIPAA-covered entities, including healthcare clearinghouses and providers, are affected by HIPAA privacy rule. When a HIPAA-covered entity uses a contractor or a non-workforce member to accomplish “business associate” activities, the Rule requires that the covered entity include certain protections for the information in a business associate agreement. This contract imposes specific safeguards on the PHI (Protected Health Information) that the business associate uses or discloses. (“Summary of the HIPAA Security Rule | HHS.gov,” 2013)

One of the most important aims of the Security Rule is to protect the privacy of individuals’ sensitive medical information while allowing covered entities to improve the quality and efficiency of patient care by adopting new technologies. Due to the extended diversity of the health care marketplace, it should be ensured that the flexibility and scalability of the design of Security Rule would allow covered entities to *“implement policies, procedures, and technologies that are appropriate for the entities particular size, organizational structure, and risks to consumers’ e-PHI (Electronic Protected Health Information)”*. (“Summary of the HIPAA Security Rule | HHS.gov,” 2013) Protected Health Information is the definition used by HIPAA to define the type of patient information that falls under the jurisdiction of the law. Billing information from doctors, blood test results, phone records, and emails to doctors which concern a health problem or a medication the patient needs are only a few examples of PHI (“Protected Health Information (PHI) - TrueVault,” n.d.). However, there are cases, such as employment records, that are not considered as PHI, and Privacy Rule does not support cover entities’ individually identifiable health information. (“HIPAA Privacy Rule and Its Impacts on Research,” 2005)

Data that have undergone the process of de-identification, *“a process that is applied to a dataset with the goal of preventing or limiting informational risks to individuals, protected groups, and establishments, while still allowing the production of aggregate statistics.”* (Garfinkel, 2016) are no longer subject to the provisions of the HIPAA Rule.

The fine for a potential HIPAA violation can reach \$50,000 per violation, while the annual maximum for repeat violations reaches the \$1.5 million. Covered entities and individuals who are accused of intentional obtainment or disclosure of PHI in violation of the HIPAA Privacy Rule, can be fined up to \$50,000 and receive up to one year in prison. If the HIPAA Privacy Rule is violated under false claims, the penalties can reach the amount of \$100,000 and the number of 10 years in prison. (“HIPAA (Health Insurance Portability and Accountability Act) | whatis.com,” 2017)

HITECH Act (Health Information Technology for Economic and Clinical Health)

On February 17, 2009, the Office for Civil Rights enacted the Health Information Technology for Economic and Clinical Health (HITECH) in order to “strengthen the privacy and security” portions of HIPAA regulations. The HITECH program authorized the Office of the National Coordinator (ONC) to “manage and set standards for the stimulus program”. (Hazard, 2017). It was created in order to prompt the implementation of electronic health records (EHR) and promote the application and the meaningful use of information technology in the area of the United States. *“HITECH Act was an ambitious effort to modernize the Health IT infrastructure to keep up with the demands of the 21st century.”* (Washington, DeSalvo, Mostashari, & Blumenthal, 2017)

The HITECH Act expanded the privacy and security protections introduced by HIPAA by increasing the potential legal liability for non-compliance and providing more rigorous enforcement. (“What is the HITECH ACT? | What HITECH Compliance Means,” 2009)

One of the issues that HITECH had to confront at the beginning was the generation of the interoperability in such an environment which characterizes from a mixed public and private economy and a sharing federal and state governing system. This kind of problems remained unsolved until today. Short-term priorities and experimentation with various models for engaging private providers, states, and health systems, constituted the main focus of the HITECH Act during the initial years of its enactment. (Gold & McLAUGHLIN, 2016)

HITECH extended the HIPAA security provisions and penalties beyond covered entities to include business associates. In the original HIPAA rule, it was stated that cover entities should get assurance from business associates they share information with, that they will protect individuals’ personal information. However, most of the covered entities neglected this rule.

HIPAA violation penalties can extend up to \$250,000, with repeat violations which remain uncorrected reaching \$1.5 million. (“What is the HITECH ACT? | What HITECH Compliance Means,” 2009; Withrow, 2010)

GDPR (General Data Protection Regulation)

The minimum guidelines concerning data processing in the EU were set by Data Protection Directive 95/46/EC until spring 2018 when it was replaced by General Data Protection Regulation (GDPR) as the primary law regulating how companies protect EU citizens’ personal data. GDPR, which was voted by the European Parliament and Council in April 2016, reinforces and clarifies natural persons’ rights in regards to the processing and free movement of natural persons’ personal data, especially in IoT healthcare applications. (“Data protection in the EU | European Commission,” 2016; Pulkkis, Karlsson, Westerlund, & Tana, 2017). GDPR regulation refers to every European Union member state and has as main purpose to protect effectively the personal information of European citizens. Through GDPR, a uniform data security law is imposed on all members of EU, so that each member state no longer needs to write its own data protection laws and laws are consistent across the entire EU. Except for EU members, GDPR regulation also concerns any company in the world that operates in the EU by marketing goods or services to EU residents. (Lord, 2018b)

Some of the GDPR guidelines are referred below:

- Subjects must allow the processing of their personal information
- Collected data should be subjected to an anonymization process in order to protect the data owner’s privacy
- Natural persons should receive information about who owns the data if a data breach takes place
- The transfer of data across borders should be secure
- Companies should add to their human resources a data protection officer (DPO) to supervise GDPR compliance

GDPR provides individuals with a notable number of rights, as they have the ability to require the revelation or deletion of their personal data from the companies that hold them. Moreover, with GDPR, there is no need to launch separate actions in each jurisdiction, as regulators, for the first time, will be able to work in concert across the EU. (Hern, 2018)

A company found in violation of the Regulation may confront significant fines and compensation fees to data subjects, which may be up to 2% or 4% of total global annual turnover or €10m or €20m, whichever is greater. (“GDPR Article 83 – General conditions for imposing administrative fines,” 2016)

Act on the Protection of Personal Information

The Act on the Protection of Personal Information is the key legislation governing the collection, storage, and use of personal information in Japan. It applies to business operators that handle personal information and has a comparable level of data protection to that of the European Union (Orito & Murata, 2005). Among others, the Act specifies the circumstances under which personal data can be collected, stored, and processed:

Processing: A business operator governed by the Act on the Protection of Personal Information must specify the purpose of use for personal information it handles (to the extent possible) and comply with the following rules:

- it must not change the purpose of use beyond a scope which has a reasonably substantial relationship with the original purpose of use; and
- it must not use the personal information beyond the scope necessary to achieve the purpose of use, without obtaining the individual’s prior consent.

Collection: The following restrictions apply to the collection of personal information by business operators governed by the Act on the Protection of Personal Information:

- proper acquisition – a business operator must not acquire personal information by deception or other wrongful means;
- notice of purpose of use at the time of acquisition – once a business operator has acquired personal information, it must notify the individual of or publicly announce the purpose of use, unless it has already been publicly announced or one of the following applies:
- such notification or public announcement would likely cause harm to the life, body, property, rights or interests of an individual or third party;
- such notification would likely harm the business operator’s rights or legitimate interests;
- cooperation with a state agency, local government or third party commissioned by a state or local agency is necessary to conduct certain affairs specified by laws and regulations and the notification, or public announcement of the purpose of use would likely impede the execution of such affairs; or
- the purpose of use is evident from the circumstances around the collection of personal information.

The guidelines issued by the Personal Information Protection Commission (PPC) include examples of how business operators can make such public announcement – namely, by posting it on their websites or displaying it in an easily viewable location within their places of business.

Business operators must not obtain sensitive information without the individual’s prior consent. Sensitive information means personal information comprising a principal’s race, creed, social status, medical history, criminal record, the fact of having suffered damage as a result of a crime, or other descriptions described by the cabinet order as those of which the handling requires special care so as not to cause unfair discrimination, prejudice or other disadvantages to the principal.

Storage: Business operators governed by the Act on the Protection of Personal Information must take security control measures in regards to personal data. The act imposes a broadly stated obligation on business operators to “take necessary and proper measures for the prevention of leakage, loss, or damage, and for other security control of the Personal Data.” The act provides no concrete measures to satisfy this requirement. However, it is generally understood that such security control measures include:

- organisational measures;
- employee-related measures (e.g., personnel training);
- physical measures; and
- technical measures.

Specific actions to be taken for each type of measure are stipulated in the various guidelines issued by the PPC.

Preventing Social Engineering

Despite the variety of technical vulnerabilities and attack methods, the weakest link in security infrastructure is people, as unintentional negligence remains the biggest risk. Healthcare Organizations should raise awareness and regularly educate their employees: Security through education is the first, main, and most effective mitigation policy. If people aren’t educated about the types of attacks being used, they have a very low possibility to defend against them. To this end, a security policy must be written and backed up by adequate awareness training. The policy must encompass clear sets of guidelines of response to any given situation. *“Absent such guidelines, employees will default to actions they perceive as helpful, which often means giving away information they shouldn’t”* (Olavsrud, 2010).

Securing Web Applications

Mitigating the risks of a perpetrator exploiting flaws in one’s web application stack is not to be considered a trivial task, as it requires vigilance and deep up-to-date knowledge through all levels and phases of the application development process. To this end, there exist well documented and continuously updated bodies of guidelines, like the one maintained by OWASP. Their recommended courses of action, regarding the vulnerabilities mentioned in a previous section, are presented in Table 3.

Preserving Anonymity

Taking into consideration the difficulties described above regarding the high cost that a possible online attack and interception of personalized medical data may entail, the imperative need for anonymization of medical information (El Emam & Arbuckle, 2013) arises. Data anonymization is the process of encrypting or removing information from a data set so that the identification of the persons is not anymore feasible. Thus privacy protection is achieved. From a legal point of view, anonymized data cease to be personal data, and as a result, their disposal does not require approval and consent (Emam, 2013). However, the process of anonymization should be done in a strict and methodical form in order to minimize the risk of disclosure. As mentioned above, the General Data Protection Regulation (GDPR) in Europe, along with the United States of America’s Health Insurance Portability and Accountability Act (HIPAA) and

Table 3. Recommended preventive actions for the mitigation of Web Application vulnerability risks

OWASP recommendations to developer teams	Related Vulnerability
Use a safe API, which avoids the use of the interpreter entirely or provides a parameterized interface, or migrate to use Object Relational Mapping Tools (ORMs). Note that even when parameterized, stored procedures can still introduce SQL injection if PL/SQL or T-SQL concatenates queries and data, or executes hostile data with EXECUTE IMMEDIATE or exec().	Injection
Use positive or “whitelist” server-side input validation.	
For any residual dynamic queries, escape special characters using the specific escape syntax for that interpreter.	
Use LIMIT and other SQL controls within queries to prevent mass disclosure of records in case of SQL injection.	
Where possible, implement multi-factor authentication to prevent automated, credential stuffing, brute force, and stolen credential re-use attacks.	Broken Authentication
Do not ship or deploy with any default credentials, particularly for admin users. Implement weak-password checks, such as testing new or changed passwords against a list of the top 10000 worst passwords.	
Align password length, complexity, and rotation policies with NIST 800-63 B's (Grassi et al., 2017) guidelines in section 5.1.1 for Memorized Secrets or other modern, evidence-based password policies.	
Ensure registration, credential recovery, and API pathways are hardened against account enumeration attacks by using the same messages for all outcomes.	
Limit or increasingly delay failed login attempts. Log all failures and alert administrators when credential stuffing, brute force, or other attacks are detected.	
Use a server-side, secure, built-in session manager that generates a new random session ID with high entropy after login. Session IDs should not be in the URL, be securely stored and invalidated after logout, idle, and absolute timeouts.	Sensitive Data Exposure
Classify data processed, stored, or transmitted by an application. Identify which data is sensitive according to privacy laws, regulatory requirements, or business needs.	
Apply controls as per the classification.	
Don't store sensitive data unnecessarily. Discard it as soon as possible or use PCI DSS compliant tokenization or even truncation. Data that is not retained cannot be stolen.	
Make sure to encrypt all sensitive data at rest.	
Ensure up-to-date and strong standard algorithms, protocols, and keys are in place; use proper key management.	
Encrypt all data in transit with secure protocols such as TLS with perfect forward secrecy (PFS) ciphers, cipher prioritization by the server, and security parameters. Enforce encryption using directives like HTTP Strict Transport Security (HSTS).	
Disable caching for a response that contains sensitive data.	
Store passwords using strong adaptive and salted hashing functions with a work factor (delay factor), such as Argon2, scrypt, bcrypt, or PBKDF2.	
Verify independently the effectiveness of configuration and settings.	Broken Access Control
Access control is only effective if enforced in trusted server-side code or server-less API, where the attacker cannot modify the access control check or metadata.	
With the exception of public resources, deny by default.	
Implement access control mechanisms once and re-use them throughout the application, including minimizing CORS usage.	
Model access controls should enforce record ownership, rather than accepting that the user can create, read, update, or delete any record.	
Unique application business limit requirements should be enforced by domain models.	
Disable web server directory listing and ensure file metadata (e.g., .git) and backup files are not present within web roots.	
Log access control failures, alert admins when appropriate (e.g., repeated failures).	
Rate limit API and controller access to minimize the harm from automated attack tooling.	
JWT tokens should be invalidated on the server after logout. Developers and QA staff should include functional access control unit and integration tests.

Table 3. Continued

OWASP recommendations to developer teams	Related Vulnerability
A repeatable hardening process that makes it fast and easy to deploy another environment that is properly locked down. Development, QA, and production environments should all be configured identically, with different credentials used in each environment. This process should be automated to minimize the effort required to set up a new secure environment.	Security Misconfiguration
A minimal platform without any unnecessary features, components, documentation, and samples. Remove or do not install unused features and frameworks.	
A task to review and update the configurations appropriate to all security notes, updates and patches as part of the patch management process (see A9:2017-Using Components with Known Vulnerabilities). In particular, review cloud storage permissions (e.g., S3 bucket permissions).	
A segmented application architecture that provides effective and secure separation between components or tenants, with segmentation, containerization, or cloud security groups (ACLs).	
Sending security directives to clients, e.g., Security Headers.	
An automated process to verify the effectiveness of the configurations and settings in all environments.	
Preventing XSS requires the separation of untrusted data from active browser content. This can be achieved by:	Cross-Site Scripting (XSS)
Using frameworks that automatically escape XSS by design, such as the latest Ruby on Rails, React JS. Learn the limitations of each framework's XSS protection and appropriately handle the use cases which are not covered.	
Escaping untrusted HTTP request data based on the context in the HTML output (body, attribute, JavaScript, CSS, or URL) will resolve Reflected and Stored XSS vulnerabilities.	
The OWASP Cheat Sheet 'XSS Prevention' has details on the required data escaping techniques.	
Applying context-sensitive encoding when modifying the browser document on the client-side acts against DOM XSS. When this cannot be avoided, similar context-sensitive escaping techniques can be applied to browser APIs as described in the OWASP Cheat Sheet 'DOM based XSS Prevention'.	
Enabling a <u>Content Security Policy (CSP) as a defense-in-depth mitigating control against XSS. It is effective if no other vulnerabilities exist that would allow placing malicious code via local file includes (e.g., path traversal overwrites or vulnerable libraries from permitted content delivery networks).	
Remove unused dependencies, unnecessary features, components, files, and documentation.	Using Components with Known Vulnerabilities
Continuously inventory the versions of both client-side and server-side components (e.g., frameworks, libraries) and their dependencies. Continuously monitor for known vulnerabilities in the components. Use software composition analysis tools to automate the process. Subscribe to email alerts for security vulnerabilities related to components you use.	
Only obtain components from official sources over secure links. Prefer signed packages to reduce the chance of including a modified, malicious component.	
Monitor for libraries and components that are unmaintained or do not create security patches for older versions. If patching is not possible, consider deploying a virtual patch to monitor, detect, or protect against the discovered issue.	
Ensure all login, access control failures, and server-side input validation failures can be logged with sufficient user context to identify suspicious or malicious accounts, and held for sufficient time to allow delayed forensic analysis.	Insufficient Logging / Monitoring
Ensure that logs are generated in a format that can be easily consumed by a centralized log management solution.	
Ensure high-value transactions have an audit trail with integrity controls to prevent tampering or deletion, such as append-only database tables or similar.	
Establish effective monitoring and alerting such that suspicious activities are detected and responded to in a timely fashion.	
Establish or adopt an incident response and recovery plan, such as NIST 800-61 rev 2 (Cichonski, Millar, Grance, & Scarfone, 2012) or later.	

the International Safe Harbor Privacy Principles in Europe and America, both give formal definitions regarding the security and confidentiality of personal data as well as their anonymization processes.

In a previous section, definitions were given for the direct and indirect identifiers that are included in medical datasets and can be exploited in order to reveal persons' identities. The main techniques used to handle the direct identifiers include either their removal from the database or their replacement with appropriate pseudonyms, depending on the purpose of the dataset (El Emam & Arbuckle, 2013). It is worth noting that, according to the General Data Protection Regulation: "Personal data which have undergone pseudonymization, which could be attributed to a natural person by the use of additional information should be considered to be information on an identifiable natural person.", that is, the pseudonymized data should not be regarded as anonymized, but rather as still personal potentially identifiable information.

Indirect identifiers or quasi-identifiers contain useful information for research and statistical purposes and as a result, are the characteristics to which data anonymization techniques aim. As the security of the data and the usefulness of the information they contain are inversely proportional, the anonymization process should follow a methodical form in order to achieve the best balance between them. The purpose of anonymization is to protect indirect identifiers and sensitive attributes from a reverse attempt to reveal the identity of the data. The techniques and anonymization algorithms are based on some basic models (Eze & Peyton, 2015). The most well-known model is k-anonymity (Samarati & Sweeney, 1998). k-anonymity ensures that every record of a dataset can't be distinguished from at least k-1 other records based on the available indirect identifiers. Therefore, any combination of indirect identifiers should either not appear at all or appear more than once in the dataset. k-anonymity protects from identity recognition, but not from field identifying and sensitive features. Another similar model that has been proposed, mainly to protect demographic components of a database, is k-map (Sweeney, 2001). It considers larger information repositories, which are called population tables and is less restrictive than the k-anonymity model but weaker in terms of security. Three new models (Gionis, Mazza, & Tassa, 2008) have been proposed, called (1, k) -anonymity, (k, 1) -anonymity and (k, k) -anonymity (k, 1) - anonymity, (k, k) -anonymity) that approximate the logic of the k-map model. They provide greater information usefulness but less security than k-anonymity and differ in assumptions about the abilities of the attackers. For the protection of field and sensitive values, the l-diversity model (Machanavajjhala, Kifer, Gehrke, & Venkatasubramanian, 2007) is used to ensure that there are at least l well-represented values for each sensitive feature, where the term well represented is usually defined by a probability threshold: an attacker can't combine his previous knowledge with any sensitive value with a probability of more than $1/l$. There are several versions of this model in the literature, such as distinct l-diversity and recursive (c, l) -diversity (Loukides, Gkoulalas-Divanis, & Malin, 2010). Other models that limit the number of distinct values of sensitive features in an anonymized dataset are (a, k) -anonymity (a, k) -anonymity (Wong, Li, Fu, & Wang, 2006) and k-anonymous p- k-anonymity) (Truta & Vinay, 2006). The t-closeness model (Li, Li, & Venkatasubramania, 2007) is also used to protect against field recognition and sensitive attributes. Accordingly, the distance of the distribution of the values of the sensitive attribute within each equivalence class from the distribution of its values to the total of data must not exceed the upper limit t.

Models have also been created for identity protection while anonymizing diagnostic codes that exist in electronic patient records. The strictest, security-wise, amongst these models, is full k-anonymity (He & Naughton, 2009) that requires at least k records in a publicized database to have the same diagnostic codes, can also be used to anonymize other codes and attributes. Other similar but more flexible models are km-anonymity (Terrovitis, Mamoulis, & Kalnis, 2008) and privacy-constrained anonymity (Loukides et al., 2010). In order to protect the field when the data set contains diagnostic codes, the p-uncertainty model has been proposed, which ensures that the probability that a person is associated with a diagnosis is less than π . Moreover, (h, k, p) -coherence (Cao, Karras, Raïssi, & Tan, 2010) and the PS-rule based anonymity (Loukides, Gkoulalas-Divanis, & Shao, 2013) models have been proposed, which prevent identification and recognition of sensitive features. The d-presence model is the one most commonly used to protect against participation recognition and specifically to ensure that the attacker can't surely know that a person is in the data repository with a probability greater than d. A similar model that does not require data holders to access all of a population's information has also been suggested (Loukides et al., 2010) and is called c-confident d-presence.

All algorithms developed for data anonymization have been based on the models described above. The way in which they process and change the indirect attributes, which is the main stage of anonymization, as well as other elements such as the heuristic strategies they use, is the information on which these algorithms can be compared and classified and finally, emerge as the most appropriate for the anonymization of a health database. (Gkoulalas-Divanis, Loukides, & Sun, 2014) present an analytical summary and classification of algorithms based on the aforementioned models. The most widespread technique used to transform the indirect characteristics of an information repository is generalization (Sweeney, 2002). In generalization, attribute values are replaced by more general ones, without altering their semantics and information they contain. When the attribute has a numerical value, it can be replaced by a range of values that contains the initial value, and if it has a categorical value, a hierarchy of generalization with a tree structure can be followed (for example, the municipality where a person is a resident can become a city or a geographical area when that is not enough, etc.). Applying generalization to all feature appearances is called global recording, while application only to specific occurrences is called local recording (Nergiz & Clifton, 2007). One form of generalization is the micro-aggregation technique (Domingo-Ferrer & Mateo-Sanz, 2002), where the values of a set are replaced with a statistical value (e.g., mean, median). Finally, the technique of suppression is essentially the abstraction of attributes or even of whole records from a set of data. It is the technique used in the direct traits, as mentioned above, but also in the indirect traits that are so rare that they can reveal the identity of certain individuals.

DISCUSSION

Taking advantage of digital health records has the potential to improve drastically clinical care, as well as facilitate data-driven research in many medical fields. However, there is always the risk to rather harm than benefit patients if data security fails to prevent successful attacks, especially given the fact that the prolific integration of technology into medical environments is continuously generating new attack vectors (Seale, McDonald, Glisson, Pardue, & Jacobs, 2018).

Security companies and regulatory authorities are making progress in the effort to tackle the prevalence of cyber-crime, but, at the same time, many healthcare organizations, often simply by delaying to invest in upgrading their systems, thus remaining constantly susceptible to new hacking technologies, are left behind in effectively securing their data, compared to other target industries. For example, (Martin, Martin, Hankin, Darzi, & Kinross, 2017) report that *“many NHS organizations spend as little as 1-2% of their annual budget on IT, compared with 4-10% in other sectors and use many run-on legacy systems that are no longer supported. Indicative of this low level of investment many NHS trusts are still using Windows XP, an operating system that Microsoft stopped supporting in 2014”*. Implementing proper security policies and procedures, is inherently difficult for the healthcare industry, given that it consists of a large number of public and private institutions and lacks the homogeneity and the coordination potential of other sectors (e.g., financial services).

In 2009 Healthcare Information and Management Systems Society (HIMSS) conducted a survey and found that, at the time of the study, despite HIPAA and other initiatives, many of the surveyed healthcare organizations *“do not perform security risk analyses and therefore do not understand their vulnerability to cyber-attack”*, their *“budgets dedicated to security remain low”*, *“still do not have a formally designated Chief Information Security Officer or Chief Security Officer to provide the needed organizational leadership to focus on cybersecurity”*, *“are not using available technologies to secure*

data, such as encryption of computer hard drives”, and “do not have a plan for responding to threats or incidents relating to a security breach” (Harries & Yellowlees, 2013).

Both Private and Public healthcare organizations should increase their efforts to protect themselves, as attacks targeting medical data will continue to increase, mindful of the potential harm to their customers/patients, to their reputation and their financial survivability (a successful breach is estimated to cost, on average, around 3.7 million dollars to clean up (Kruse et al., 2017)). It is therefore imperative that the necessary time and money are invested towards ensuring that healthcare organizations’ software systems are adequately protected, developed, implemented and maintained for the ability to keep sensitive data private and prevent them from falling into the wrong hands.

In order for the new healthcare paradigms to thrive, the public’s trust is imperative. Almost all of the modern medical tools employing personalized care principles and informed evidence-based clinical decisions are based on systems’ interoperability and flexible data access which, in turn, need acceptance, trust, and consent on both personal and social level. Depriving medical practice of these tools due to distrust and fear can render it obsolete. Thus, one could argue that unsuccessful attempts to protect health data have an indirect but significant impact on the quality of the provided healthcare.

KEY TERMS AND DEFINITIONS

Anonymity: Anonymity and thus anonymous data is any information from which the person to whom the data relates cannot be identified, whether by the company processing the data or by any other person.

Cloud Computing: Cloud computing is a type of computing that relies on shared computing resources rather than having local servers or personal devices to handle applications.

Cyberattack: A deliberate exploitation of computer systems, technology-dependent enterprises and networks.

GDPR: General Data Protection Regulation is a new set of rules governing the privacy and security of personal data laid down by the European Commission.

Private Health Data: Is defined as individually-identifiable health data, which is exquisitely sensitive. Being linked to an individual, the private health data can only be shared with the permission of the individual.

The Emerging Threats of Web Scrapping to Web Applications Security and Their Defense Mechanism

INTRODUCTION

Nowadays the Internet is at its peak everything is available online or is going to be available soon. So the Internet has provided us with some facilities like online Shopping, Bookings of trains and buses tickets, education and many more. However, there is always another side to the coin, with the facilities comes the cyber attacks of various types like DDOS, Man in the Middle, SQL Injection etc. One of them is Web scraping which is a very serious issue nowadays it's affecting the market of online e-commerce at very great extent.

It is an ongoing threat that aims to take sensitive data from a victim or from web applications. According to the Automated Threat Handbook for Web Applications published by the Open Web Application Security Project, web scraping is exploited at companies in industries including education, financial institutions, government agencies, hospitals, and retail (Munzert et al., 2014).

The main objective of this chapter is to scrutinize to what degree web scraping can cause a threat to web application Security. In first section the terms in the chapter are defined, and an adequate overview of web scraping in context to web application security is presented in order to provide the reader with an understanding of the background for the remaining sections.

The next section examines the classification of web scraping such as content scraping, web scraping, price scraping, data aggregation, database scraping in general and reviews the most widely used scraping tools such as Visual Web Ripper, Web Content Extractor, Mozanda Web Scraper and Screen Scraper.

A section dedicated to Defense Mechanism including detective and preventive mechanisms are presented. Subsequently, the aim of this chapter is to provide review of vulnerabilities, threats of web scraping associated with web application applications and effective measures to counter them.

WEB SCRAPING

Web scraping is also known by some other names like web harvesting and web data extraction basically is used for extraction of data from the websites on the WORLD WIDE WEB. In other words, it can be defined as the process consisting of the extraction and combination of content gathered from the web in a systematic manner (Vargiu & Urru, 2012).

Software applications are available for doing the web scrapping which may do their work of accessing the World Wide Web using Hypertext Transfer Protocol or web browser. Web scraping can also be done manually by the user but is preferably done in an automated fashion implemented using a bot or web crawler. In this, some software also known as web robot is mimicking the browsing between the web and the human in a conventional web traversal.

This robot may gather the data from as many websites as needed and the parsing of the contents is done to easily find and fetch the data required and stores them in the structures as desired.

Generally, this task of web scraping is somewhat similar to copying; in this particular data is collected and copied from the Internet into some manageable and readable storage structure like some spreadsheets or databases.

In this process, the web page is downloaded or fetched (it happens whenever the browser opens up some pages) first and saved for later use and then the data is extracted from it. Hence we can say that web crawling is an important component of the process.

At the second step of the process the content present in the page is parsed, searched or some type of reformatting is done to understand the content for the data to get it inserted into the spreadsheets or database by copying. Generally, the web scrapping software may sometime take a part of the page which can be useful for the authority for some other purpose.

Web Scrapping is being used in various things in today's life like in advertisements and marketing generally by contact scraping and also an important part of the application made for data mining and web mining, and sometimes used to do some price comparisons, for online price change monitoring, weather data monitoring, research and for providing a service to the user where the content comprises of more than one source also known as web mashup for instance, like trivago and mybestprice applications.

Basically, these web scrapers are APIs which are used to extract data from a web page or a website present on the Internet. Also, some big companies like Amazon Web Services and Google provide web scrapping tools free of cost to end users.

Nowadays a new form has been also used for web scrapping which consists of listening or monitoring the data feed from the web servers. And also some web scraping systems are also using DOM parsing techniques, computer vision and NLP to simulate human browsing as to pass the checks for bots that some websites are using to prevent web scrapping.

Types Web Scrapping

There are various types of web scraping. This section explores the categories of widely used web scraping techniques. These are Data Scraping, Content Scraping, Price Scraping, Database Scraping, News Scraping, Article Scraping and Email Harvesting

Data Scraping

It is a process in which computer program gathers data from some humanly understandable output that is coming from another computer program. Generally, data transfer between programs is done using various data structures best for processing by computers, not humans. These interchangeable formats and protocols are rigid in structure, mostly well documented and easy to parse.

The main difference between data scraping and parsing is just that it scrapes the data which was for display for humans and was not used as input to another program. It ignores data in binary format. It is mostly used as an output to a legacy system which has no other way by which it can display the data or it is used for the systems for which the APIs are not good enough to provide the data. It is not the most preferable technique to be used to extract the data; it is usually the last option when no other technique is available (Yang et al., 2010).

Content Scraping

It is generally the technique of lifting off the displayed content from various websites and using it somewhere else or displaying it on other website. The technique is illegal as it is generally done without the permission of the original source. The content scrapers mostly copy the whole content being displayed and share it as their own content. It is an illegal method to steal the content from a trusted website and publishing to another website without the knowledge of the content's owner (Cormode & Krishnamurthy, 2012).

Content scraping is being done at the expense of the website that has invested time, resources and money as it will also affect their SEO ranking. It can be done by manually copying and pasting or by using special software or by HTTP programming etc.

Price Scraping

The technique of extracting or collecting the prices of various sellable things available over the internet on various websites without the consent of the corresponding authorities and slowing down their network by frequently requesting for the data being displayed by them. It is generally used to beat the competition in the market or to make profits out someone's loss by planning according to the scrapped data and lowering the prices of things being searched by users to attract them to their own website and increase their profits through ads being shown on the website (Rahman & Tomar, 2018).

Price scraping can be done for various uses in order to predict some share of the market being occupied by the biggie of e-commerce or for the newcomers to know about the various new trends being prevailed in the market in order to enter the competition of selling things online and also to gather the information about the supply and demand of various products being sold on the website.

It's illegal to scrape the data for commercial use but still, it is being done by many companies for various purposes and there are no efficient methods present to have a check on it (Parikh et al., 2018).

Database Scraping

The technique of directly extracting data from the database is known as the Database scraping. Sometimes the data is being stored in the database file or .csv file in which the data is being stored in the structured format for some special use or classification to do some calculation etc.

The data is being stored in columns and rows so there may not be difficulty in scraping the data as the data has some pattern that is stored. It can be used for various purposes but is basically used for research purposes as a large database are being scraped off data to classify the data into some important information which can help in predicting the results of some work or to provide automation.

Sometimes it is also used for commercial purposes in order to scrape the database of persons personal details without his/her consent. So it can be used for illegal as legal purposes (Mitchell, 2018).

News Scraping

The techniques of scraping used for scraping the news from the newspapers websites is known as news Scraping. The articles of news are being scraped to some blogs or some database in order to do some discussion or to have the database of the news which can be used to predict the type of acts of crimes can happen or to calculate the results of the distribution of the crimes happening.

It can be used by some educational purposes in order to be updated on the various things happening or we can say enhance student's general knowledge in preparation of various exams. It generally doesn't affect much but it lowers the ranking of the website SEO rankings and the Web ratings and the traffic on the website will be affected accordingly (Pak, 2017).

Article Scraping

The scraping of the data being written over blogs or various websites on the internet is known as Article scraping. Generally done for the purpose if the collection of data that can be used for various purposes like educational, research etc.

This practice can be used for some type of security purposes sometimes in order to find some potential threats to the nation or some specific words being used against some things of political importance or It can be used to ease the process of collecting data on some specific topic which is new and evolving and to improve the related information on that specific topic in order to provide reliable information which can be used further for various process developments and experiments (Ou-Yang, 2013).

Email Harvesting

The mechanism to obtain a large number of email addresses using different methods or techniques. The main purpose of email harvesting is for spamming or advertising purpose.

It is mostly done by some specialized harvesting software or programs also known as the harvester. The email can be scraped using various ways like from mailing lists, stored data of a web browser, from yellow pages through social engineering etc. Some spammer use the dictionary attack to extract an email address, in this the valid emails addresses are found by means of guessing the most used usernames .or by offering a product or service to users absolutely free till they provide their genuine email address and then from them collect email addresses for spamming or bulk email (Polakis et al., 2010).

Figure 1 .The products page of an e-commerce website

AUTOMATED WEB SCRAPING TECHNIQUES

Text Pattern Matching

It is a method of doing the extraction of data from the parsed web page in the process of web scraping by using the Regular Expression matching in the collected data.

Regular Expression can be defined as a sequence of characters that define a search pattern. Generally, this can be used by various algorithms of string searching to be used on strings and for validating some inputs taken by the user (Usmanov, 2017).

A regex processor is the breaks down the regular expression into an internal representation which is executed and matched for a string that represents the text that is searched in. An easy way to specify a finite set of strings is to list its members. For example

There is a set containing two strings “Handel”, “Haendel” can be matched by the pattern **H(alae?)ndel;**

The regular expression is widely used in UNIX. There is a module represent in python which provides full support for PERL-like regexes. The whole process of doing web scraping can or can't have a regex in your implementation of the scraper. It depends on the type of website being scraped and is the last resort to do the scraping when no other methods can be used in order to scrape the useful data from the website. It is generally used when there is no pattern defined in a website or the data is randomly given and there is only some textual pattern present in the website.

For example in Figure 1, the products page of an e-commerce website is shown and in Figure 2 its corresponding HTML code

For this particular website having price as a text on the buttons of the products along with the Symbol “Rs.”. To scrap or extract the price of product from this webpage following script is executed in python shown in figure 3.The snapshot of the outcome is shown in figure 4.

HTML Parsing

As we know every website present on the internet are written using HTML (Hypertext Mark-up Language).As it is a structured language so that implies that every web page is a structured document. And sometimes we might need data from the websites and web pages and preserve their structure as well.

Figure 2. HTML code of products page of an e-commerce website

```

<div class="card">
<div class="card-image waves-effect waves-block waves-light">
<a href="product.php?pid=EG0051"></a>
</div>
<div class="card-content">
<span class="card-title activator grey-text text-darken-4">Mini wax dolls<i class="material-icons right">more_vert</i></span>
<p><a href="product.php?pid=EG0051" class="btn amber waves-light btn">Rs.5000</a>
</p>
</div>
<div class="card-reveal">
<span class="card-title grey-text text-darken-4">EG0051<span class="pnmsize">(Mini wax dolls)</span><i class="material-icons right">close</i></span>
<p>Wax miniatures- can be done for any picture.</p>
<a href="product.php?pid=EG0051" class="btn btn-large amber waves-light btn" style="font-size:22px; font-weight: bold;
<i class="material-icons left">shopping_cart</i>Rs.5000</a>
</div>
</div>
</div>

```

Figure 3. Python script for price scrapping from products page of an e-commerce website

```

# import libraries

import bs4
import requests
import re

res = requests.get("http://<examplewebsitename>/")
soup = bs4.BeautifulSoup(res.text, 'html.parser')

print(re.findall(r'Rs\.[0-9]+\.', res.text))

```

Figure 4. The snapshot of the outcome of Python script for price scrapping

```

['Rs.5000', 'Rs.5000', 'Rs.1250', 'Rs.1250', 'Rs.850', 'Rs.850', 'Rs.600',
'Rs.600', 'Rs.1500', 'Rs.1500', 'Rs.1100', 'Rs.1100', 'Rs.2000', 'Rs.2000',
'Rs.1200', 'Rs.1200', 'Rs.450', 'Rs.450', 'Rs.1399', 'Rs.1399', 'Rs.2000',
'Rs.2000', 'Rs.450', 'Rs.450']

[Done] exited with code=0 in 1.951 seconds

```

In general, parsing is basically to break (a sentence) into its components and specify their syntactic roles. Parsing or syntactic analysis is the process of analyzing a collection or string of symbols can be in the natural language or in a computer language agreeing to the rules of a formal grammar.

In this case of HTML parsing comprise of:

Taking in HTML code and extracting needed information like the title of the page, paragraphs in the page, headings in the page, links etc.

The request will be made to get the web page using request module get function and then the extracted HTML script will be converted into HTML tree which will have the structured data from that we will make use the various ways to go over that tree like XPath or CSSSelect and then the extracted t=data will be added to the various lists.

The lxml is a pretty extensive library written for parsing XML and HTML documents in no time and can also handle messed up tags in the process of parsing.

There are two ways to extract the data from the web page after being converted into HTML tree by using XPath or CSSSelect. This example will make the use of XPath. XPath is a way of locating information in various structured documents like HTML and XML.

DOM PARSING

As we have explained parsing in the previous techniques. There are two types of parsers present

Top-Down Parser

Top-down parsing can be seen as a dry run to find the left-most derivations of an input stream by looking for parse trees using a top-down opening out of the given approved set of grammar rules. Tokens are generally put to use from left to right.

Bottom-Up Parser

A parser can begin with the input and tryout to rework it to the start symbol. The parser attempts to detect the most primary elements than the elements comprising of these and so on.

DOM stands for the Document Object Model is a programming API for HTML and XML documents or web pages. It specifies the logical structure as well as the way to access the document and manipulate it.

With DOM developers can create and build documents, navigate through their structure and can add, modify or delete content or elements.

In Document Object Model, documents consist of a tree-like logical structure or a forest comprising of more than one tree. In this, the documents are modeled using objects and the model contains not only the structure of the document but also the behavior of a document and the objects which it comprises of.

While scraping a website the first step is to request the web page and receive the page HTML DOM tree. After this, the step is to parse the DOM tree to extract the data we want. Usually, it is done with string operations and using regular expressions. The other methods are by using DOM parser library either CSSSelect or XPath to extract the DOM elements which contain the required information.

Optical Character Recognition (OCR) Techniques

Optical Character Recognition techniques can be used for images or documents which cannot be parsed into text directly which contain some information required.

It is the mechanical or electronic conversion of images of typed handwritten or printed text into machine-encoded text. It is widely used for solving CAPTCHA's (Completely Automated Public Turing test to tell Computers and Humans Apart)

Which is used as the preventive measure for the web scraping done on the web pages on various websites. The OCR technique is useful in some web pages where the required information is in some images or PDFs so to scrape that required information this technique is used. It is not much efficient but is constantly worked upon to increase its efficiency to help in scraping and various other streams (Cheng & Evans, 2012).

There are four types of Character Recognition Techniques:

1. **Optical Character Recognition (OCR):** Generally targets typewritten text, one glyph (an elemental symbol within an agreed set of symbols, intended to represent a readable character for the purposes of writing) or character at a time.
2. **Optical Word Recognition:** Targets one word at a time (generally for languages use a “ ” as a word splitter)
3. **Intelligent Character Recognition (ICR):** Targets handwritten print scripts or cursive text one glyph or character at a time using Machine Learning.
4. **Intelligent Word Recognition:** Targets one word at a time. Mostly used for languages where glyphs are not separated in cursive script.

LEGALITY OF WEB SCRAPING

The legality of web scraping depends upon the type of data you are scraping from the website and how you use it. For ex:- the hotel booking app like Trivago scrape the prices from all the other hotel booking website and compare it only so it is legal but if it scrape the data and show its prices less than other sites in order to increase its own customer base then it become illegal.

In general if the information scraped is available to public is used in friendly way it is legal. Site like LinkedIn sue the people who try to scrape their site without permission and reasons are:-

1. Breach of Contract
2. Misappropriation
3. Trespass
4. Violation of Computer Fraud and Abuse Act

So to not get in trouble while scraping data from any website one should try to follow these advices:

1. Respect the Terms of Service
2. Obey the rules of Robot.txt
3. Use an API instead of scraping data
4. User Agent field must be filled with right information
5. Do not try to publish your scraped data on public platform until you have the permission to do so.

WEB SCRAPING TOOLS

Scraping of data from any website in large extent is very hectic task and consume a lot your time. So, it can be done with the help of various tools which helps us to extract the information from web very easily. These tools can be used to compare prices of products, scrape user profiles from various social network sites, monitor the real estate prices etc. There are various tools present in the market which are used to scrape the data from websites. For example:-

1. Visual Web Ripper
2. Web Content Extractor
3. Mozenda Web Scraper
4. UI Path-Robotic Process Automation
5. OutWit Hub
6. Screen Scraper
7. WebHarvy
8. Easy Web Extract
9. Scrapy
10. Import io

Visual Web Ripper

Visual web ripper is the powerful visual tools used to scrape the data from any website automatically. It walk through the whole website and collects the needed the data like product catalog, search information etc. Also it saves the data in structured form in spreadsheets as CSV or XML file. It runs on the scheduled basis so the data extracted remains up to date. It is very easy to use as you can extract the data by just clicking on the data element. Anyone having good .NET programming skills can easily use this tool into their own application (Haddaway, 2015). The features of this tool are mentioned below:-

- It extracts the whole data and saves it in structured form.
- Very user friendly.
- Harvests data undetected.
- Command line processing and comprehensive API.

Web Content Extractor

Web Content Extractor can be used if anyone wants to extract typical data from multiple web pages. It is designed to increase the productivity as well as the effectiveness of data scraping. It does not require and coding but it provides point and click web interface.

Web Content Extractor allows a user to scrape the data even from the cloud. It is accessible from any web browser on any operating system (Herrouz et al., 2013). Some of the features of Web Content Extractor are mentioned below:-

- Reliable and powerful extracting tool
- User can configure to work on specific links and it helps in accurate web scraping.
- User just has to specify the data extraction process which can be done by few clicks and from that the extractor will do the rest of the work.

Mozenda Web Extractor

The following approach is followed by this software to extract the information (Agrawal & Agrawal, 2013). The Working of Mozenda Web Extractor is shown in Figure 5.

Figure 5. Working of Mozenda web extractor

- **Identify, Build and Collect:** Extract files, images, text and PDF content from the web pages and transform them into the structured form.
- **Structure, Organize and Publish:** Organize and prepare the data files for publishing. User can transport information directly in CSV, XML and JSON files.
- **Analyze, Visualize and Decide:** Collect and publish your web data to your preferred BI Tool or database.

UI Path- Robotic Path Automation

Robotic Path Automation is the technology with the help of which anyone can configure the computer software. Also it can be described as robot working in the form of human in order to execute some business process. To capture the data and manipulate it the RPA robots uses the user interface. RPA robots never sleeps and makes no mistake.

Works that can be performed using RPA robots are:

1. Log into an application
2. Connect to system API
3. Copy and paste data
4. Move files and folders
5. Extract and process structured and semistructured content from documents, PDFs, emails and forms.
6. Read and write to database
7. Scrape data from web
8. Make calculations

Various features of RPA are:-

- Fast implementation
- Reduce the manual effort
- Improve customer service

OutWit Hub

OutWit Hub breaks down the content of webpage into different constituents so that it can navigate through the different pages automatically, extracts data and organize the extracted data into the usable collection.

This tool can be accessed by anyone whether a person wants to scrape the specific data or just a particular document, image etc. A person without any programming knowledge can see the extracted data easily. Extracted data can be transported to CSV, Excel Spreadsheets, HTML files etc. and are directly saved onto the user's hard disk. The latest version of this software is 7.0.0.56 and is available for free download.

Screen Scraper

Screen scrapping is a process in which data from one screen of any application is scraped and shown on the display of another application (Holmberg et al., 2015).

Screen scraper provides the web scraping services. Firstly you have to decide what to scrape from the web i.e. Text, images, data etc. then user chooses the type of file extension in which he/she wants the data to be organized and then screen scraper will do the rest of the work for you.

WebHarvy

WebHarvy is software which is used to scrape the data. It has various features (Johnson & Gupta, 2012):

1. **Easy Data Selection:** Similar to Web Content Extractor it has point and click interface which makes it easy to use. No code or scripts are required to scrape data.
2. **Intelligent Pattern Detection:** If data repeats itself like names, address, phone number etc. There is no need to configure the software but it automatically detects the pattern and scrape the data for you.
3. **Save to file and database:** Similar to other softwares you can save the scraped data in any form of file like Excel, CSV, XML etc.
4. **Crawl Multiple Pages:** If any of the data is displayed in multiple pages then you can easily extract data with the help of WebHarvy. You have to provide the link of the next page and then WebHarvy can extract data easily.
5. **Safeguard Privacy:** Sometimes web scraper softwares get blocked due privacy issues in some sites. To prevent this problem WebHarvy uses the proxy server so that it can scrape data without any hindrance.
6. **Regular Expression:** A user can apply regular expression on text or HTML source and scrape the matching data. This feature provides the flexibility to user while scraping data.

Easy Web Extract

Easy Web Extract works in three steps (Abburu & Babu, 2013):

1. **Web Data Pattern Specifying:** In this phase the user tells the software what data to scrape and from where.
2. **Automate Scraping Web Data:** After the step-1 software will automatically find proper urls and extract information based on the data pattern.
3. **Export Scraped Data:** The scraped data is stored in to the files which can be of various extensions.

Scrapy

Scrapy is an open source and collaborative framework which is used to extract the data from a website. It requires web crawlers to be designed by user and run it over any website to scrape the data (Myers & McGuffee, 2015).

Example of code which scrape the quotes from a website <http://quotes.toscrape.com>.

```
import scrapy
class QuotesSpider(scrapy.Spider):
    name = "quotes"
    start_urls = [
        'http://quotes.toscrape.com/tag/humor/',
    ]
    def parse(self, response):
        for quote in response.css('div.quote'):
            yield {
                'text': quote.css('span.text::text').extract_first(),
                'author': quote.xpath('span/small/text()').extract_first(),
            }
        next_page = response.css('li.next a::attr("href")').extract_first()
        if next_page is not None:
            yield response.follow(next_page, self.parse)
```

Put the above code in file named quotes_spyder.py and run the spider using runspider command:

```
scrapy runspider quotes_spyder.py -o quotes.json
```

When the above command finishes you will get quotes.json file which will consist of scraped quoted from the above mentioned website.

ImportIO

ImportIO is the company which develops the data extraction or scrapping software. Its data extraction technique is machine learning based and no coding is required to extract data (Mitchell, 2013).

Features of ImportIO extractor are:-

Figure 6. Snapshot of browser window for price scrapping

1. Point and click training
2. Machine Learning Auto suggestion
3. Get data from behind login
4. Webhooks (where you want to store data)
5. Extract data from multiple pages
6. Auto optimized Extractors
7. Control via API or UI
8. Extractor Tagging

Attack Scenario of Price scrapping

The system which we have developed mimics the actual scenario in which the scraper attacks any website and what mechanism can be used to detect the presence of the bot on the website. The System comprises two Subsystems:

Attack System

The attacking scenario contains many steps on the type of scraping is done. Here to do the price scraping we have to build the scraper in three parts

1. GUI Graphical User Interface
2. Web Crawler or Spider
3. Web Scraper

Graphical User Interface

The GUI refers to some type of visible program output, with which the user can interact to give the input to the scraper to do price scrapping. In this, we have used the libraryTkinter in python 3. In this, we have made a simple Browser window consisting of one input field which takes the input from the user of the website to be scraped off the price and then there is a button named label “go” is present which

Figure 7. Working of spider

Figure 8. Working of web scraper

starts the spider and sends the URL of the website to the spider. The snapshot of Browser Window for Price Scrapping is shown in Figure 6

Spider or Web Crawler

In this spider, the basic work that is done is to collect all the links present on the websites that belong to the website only. The process of crawling the entire website is a very complex process as nowadays we know that the single website contains a great number of links present in it or have a very high amount of pages present in the website. So we have to make a web crawler which is efficient and speedy too that increases the difficulty of the making of spider very much.

So to overcome this problem, we have to divide the work into different workers or spiders. This can be done by using threads in the making of spider which can divide the work in them and can specify the work. This is an efficient process to specify the process but it creates one more problem of inconsistency and redundancy as well as various Spider will try to access the same link and will do the scraping or crawling of the web pages multiple time which is a waste of resources and time as well. So there is one solution to this problem that we are facing that if we can make only one instance of the links queued and one instance of links to be crawled so that every spider knows which link to pick out of the queued ones. When the process of the spider comes to an end the process of the scraping begins. All those crawled

links of the website are stored in some temporary memory or in a file which can be accessed by the scrapper after the crawling is being done. Figure 7 shows the working of spider.

Web Scraper

The scraper takes the input of the links which has been crawled by the spider and starts the scraping of data in the following ways. The overall working of Web Scraper is shown in Figure 8.

Step1: Review

It is the most important step of the web scraping as all of the further process depends on this step. Because it is the step in which the structure of the web page is analyzed and the most effective techniques of scraping are decided as to how to scrape the data or in which way we can filter out the data from the web page.

Step 2: Access or Document Load

In this step, the page is requested from the server and the page downloaded from the internet in order to parse it into a string of characters. Then there comes the HTML parser which converts the downloaded page into Document Object Model so the scraper can scrape out the data from the structured document easily by accessing various techniques HTML tags and Dom objects.

The requests library can be used to and the get method:

```
from requests import get  
response=get(url)
```

Step 3: Parsing

Once the page is parsed into the required document or data then it is analyzed for any type of pattern present in the document where the required data is being stored in the document as finding some pattern will ease the process of filtering the information out of the data or the document.

The libraries it can make use of are BeautifulSoup and HTML Parser

```
import bs4  
soup = bs4.BeautifulSoup(response.text, 'html.parser')
```

Step 4: Extraction

Then there comes the process of filtering the data out or scraping as we know there are various steps of filtering the data is through Regular expression, accessing the DOM object or by accessing the Html tags etc. But it depends on the placement of the data inside the HTML page just loaded on to the buffer. So different methods are applied to filter out the data sometime the methods are combined to do the scraping.

```

req = requests.get('http://<examplewebsitename>/')
soup = bs4.BeautifulSoup(req.text, 'HTML.parser')
elements = soup.find_all('div', {'class': 'card-content'})
record = []
for element in elements:
    name = element.span.contents[0]
    price = element.p.a.text
    price = price[price.find('Rs.')+3:-1]
    pid = element.p.a['href']
    start = pid.find('pid')+4
    prodId = pid[start:-1]
    record.append((prodId, name, price))

```

Step 5: Transformation

After the data is filtered out the structured or meaningful information is present on hand which has to be stored somewhere in order to use that information in near future. So the data can be stored in various places like in CSV files, database, cloud and many more. the data is stored in forms of tables mostly as it is easier to classify that data for further use in various things.

The pandas module can be used to store the DataFrame of the data:

```

import pandas
import os
records.append((ip, date, method, byte, name))
df = pandas.DataFrame(
records, columns=['ip', 'date', 'method', 'byte', 'name'])
df.to_csv('logdata.csv', index=False, encoding='utf-8')

```

This is the whole process of scraping the data off the website we are generally taking the case of price. So the main websites will be consisting of the various e-commerce website present on the internet. There are thousands of e-commerce websites present on the internet which can be scraped for their data. This data can be used to enhance one's business by getting the lowest price for the things being searched or posted on his/her website. And increasing the hits on the website and also increasing the customer market and the profit by selling these things on the fewer prices than the competitor websites.

DEFENCE MECHANISM

Scraping is very useful when we want to scrape large amount of data from any website as it saves our time and resources but sometimes people make the wrong use of this technique. For instance, we have two online e-commerce website which are competitors. Owner of first website take the prices of another website using scraping techniques and show his prices less than other which is illegal. In order to get rid of this problem, some defense mechanisms are designed. These defense mechanisms are of two types:-

1. Preventive Approach
2. Detective Approach

Preventive Approach

This kind of approach is used to prevent the bots from entering into the websites and stealing the important data. Various sites including Google, Amazon, Coursera etc. uses this approach for their data safety. Various techniques of preventive approach are:-

1. Manually
2. CAPTCHAs
3. Geo-Fencing
4. Flow Enforcement

Manually

During web scraping attacker HTTP request your server which further sends back the web page to the program. The attacker parses this HTML and extracts the required information. This process is repeated over and over again so that all the required information can be extracted from the website.

In order to get rid of this problem the webmaster can follow some steps:-

1. **Take a Legal Stand:** A person can clearly mention that web scraping is not allowed on this website. For instance Medium's terms of services contains following line:-

Crawling the Services is allowed if done in accordance with the provisions of our robots.txt file, but scraping the Services is prohibited.

The owner of website can take legal action against the potential attacker.

2. **Prevent Denial of Service(DoS) Attack:** After putting the legal notice there is a chance that attacker will again attack on your website. He/She can cause disrupt the daily services of your website causing DoS attack on your servers. To avoid this kind of situation you can detect the IP address of attacker and can block the requests coming from this IP address.
3. **Using .htaccess File:** .htaccess is the configuration file of Apache web server and it can help to prevent the scraping of your data. First you have to detect the attacker using Google Webmasters and then you can stop the attacker by doing some changes in configuration file.

CAPTCHAS

CAPTCHA stands for Completely Automated Public Turing test to tell Computers and Humans Apart. This technique is used to detect whether the person entering the website is a bot or human with the help of images or text (Rahman et al., 2012). We can see when we enter any website it asks to write the text written in distorted form, this type of CAPTCHA was invented in 1997 by two parallel groups. CAPTCHA is efficient technique to prevent web scraping but sometimes it irritates the user also.

- You can design your own CAPTCHA by writing few lines of code but it is easier to use something like Google's reCAPTCHA in which user have to only tick a radio button and he can enter the website easily.
- If you are making your own CAPTCHA, try to hide its solution. If you provide the solution of CAPTCHA in its code it will become easier for attacker to decode it.
- Image CAPTCHAs can irritate the user easily as if there is some fault detected it will appear again and again.

Geo Fencing

Geo fencing is a technique in which websites are exposed only in some specific geographical regions where they do their business. This will not stop the web scraping but the attacker has to make extra effort because they have to run their web scraper over a specific geographic location. The attacker has to use the VPN link to a local Point of Presence (PoP-: Point at which two or more network build a connection between them) (Xing & Sieber, 2018).

Detective Approach

The Detective Approach is used to detect the bots entering into the websites to steal data and take defensive steps according to the behavior of these bots. Various techniques can be followed to stop the scraping of data (Rahman & Tomar, 2018).

1. Machine Learning Approach
2. Robots.txt Access Approach
3. User Agent Check
4. IP Address Approach

Machine Learning Approach

In machine learning approach we detect the behavior in which the bots are stealing our data. We take a dataset which includes the information about uses to differentiate between bots and humans. Database includes fields like time spent on a site, files scraped by any user etc. This database is passed to the supervised ML phase in which there are two phases like training set and testing set.

In training set the machine will be trained using above explained database and various training models like Naive Bayes, Decision Tree, SVM etc. and then testing will be done on other data. The machine learning process is shown in Figure 9.

Robot.txt Access

The Robot Exclusion Standard allows the Web Administrator to specify the part of site which is off-limits. Robot.txt includes the files specified by Web Administrator which are off-limits for robots which are going to attack the site. So, whenever robot visits any site, it should examine this file first. For instance, when a bot visit www.abc.com, the robot.txt file is accessed using the URL: <http://www.abc.com/robots.txt>.

Figure 9. Flow chart for the machine learning approach

Let us consider that the robot.txt file contains file named X.html which is not allowed to get accessed by the robot. But when bot comes to the site is scans each and every file related to the website. It will also go to X.html file and the bots get detected easily when they try to access robot.txt file. Any website does not provide direct hyperlink to this file from any HTML page, so many users are unaware of these files.

User Agent Check

When the bots do not work fine while scraping data it can cause the DoS(Denial of Service) and server will not be able to fine and there will be overloading on server. It is required to have a beneficial relationship between Web servers and bots. To establish a good relation between server and bot, the robot must declare its identity to the server. The User Agent field plays an important role which contains the identity of bot including its name. Sometimes bot designer uses user agent fields as that of Web browsers and detection of bot becomes very difficult.

IP Address Check

Another way to detect a bot is to match the IP address of Web client with web bots. This approach is not much useful as compared to other because the World Wide Web expands; it has become difficult to keep the record of all the bots coming onto the site. Also sometimes the web client uses the same IP address as that of the web bot. This approach is applicable only if the robot has been detected earlier. This doesn't mean that new robots could not get detected; new robots can be detected by examining the

top visited IP address and manually checking the origin of all the IP addresses. This approach is very time consuming and require more time and efforts than any other approach.

CONCLUSION

As described in the chapter, although there are great advantages of using web applications but there are lot of practical issues related to web application security needs to be answered. Similar to any technology, several security issues confront web applications. In this chapter security mechanism of Detective approaches and preventive approaches of web applications from web scrapping are reviewed, and the primary characteristics and elements of web scrappers are also explored. It is come out that scrapping attacks have a severe impact on web applications and the attacks may lead to the serious problem for web applications. Nearly all key attacks of scrapping in web application along with the feasible impacts and the existing countermeasures have been explained.

KEY TERMS AND DEFINITIONS

Article Scraping: It is a process of scraping of the articles from the blogs or websites.

Content Scraping: It is a process of lifting off the displayed content from various websites and using it somewhere else or displaying it on other websites.

Data Scraping: It is a process used to extract massive amount of data from websites in which the data is stored in local computer system or in structured database.

Database Scraping: It is a process of directly extracting data from the database is known as the Database scraping.

Email Harvesting: The mechanism to obtain a large number of email addresses using different methods or techniques.

News Scraping: It is a process of scraping the news from the newspaper websites.

Price Scraping: It is a process of extracting or collecting the prices of various items in e-commerce site available over the internet without the consent.

Web Scraping: The process of extracting data from the websites in a systematic manner.

Social Engineering Using Social Networking Sites

Roberto Marmo

University of Pavia, Italy

INTRODUCTION

The protection of information is of vital importance to organisations and governments, therefore the development of measures to counter illegal access to information is an area that receives increasing attention. Information security is the specific discipline that regards the state of being protected against the unauthorized use of information, especially electronic data, or the measures taken to achieve this.

Even though the effectiveness of security measures to protect sensitive information is increasing, the human element remains a weak link because people remain susceptible to manipulation in order to obtain unauthorized information. Social engineering is the art of using human skills and persuasion techniques to obtain unauthorized information and to gain access to a myriad of sensitive services and data is called. Social networking sites are an ever more popular way for people to stay connected, in touch with other people across the globe, therefore a lot of social data are publicly available, a useful source of data to attackers.

The aim of this contribution is to describe some technologies and methodologies to execute social engineering using social media as specific approach, it also discusses background, knowledge, challenges and critical factors necessary for successful implementation or detection.

Background

A social network is a social structure made of individuals (organizations, company ecc.) also called nodes, which are connected by links represent relationships and interactions between individuals. Social networking sites are an ever more popular way for people to stay connected, in touch with other people across the globe. They become an integral part of personal lives. Business opportunities are formed and lost online. Social network is capable of holding all the private information that one feeds it with. It is thus the responsibility of a user to be accountable of the content one posts via the network.

Persuasion has always been part of human interaction. It can be used to influence and support good or improved behavior (Martin, 2014), but it can also be used to trick and manipulate people into performing actions that can end in some kind of loss, divulging confidential information (Mitnick, 2002) or giving money to fraudsters.

The brain creates routines, which can help deal with and process things more efficiently. But these routines can also compromise the ability to pay attention and to cause the brain to bypass details which would help detect fraudulent content. In addition to that, people generally believe that they are good at detecting social engineering attacks. Research, however, indicates that people perform poorly on detecting lies and deception (Qin, 2007; Marett, 2004).

DOI: 10.4018/978-1-5225-9715-5.ch054

Social Engineering

4

Social engineering is a process that cyber criminals use to psychologically manipulate an unsuspecting person into divulging sensitive details through the use of specific techniques. This approach is not enough to breach the security of an individual or a company, it is a fundamental step to obtain useful information to execute some successive malicious activity.

Social engineering is an extremely powerful tool that can be deployed to bypass complex and secure infrastructure and systems. It is superior to most other forms of hacking in that it can breach even the most secure systems, as the users themselves are the most vulnerable part of the system. Instead of technical attacks on systems, cyber criminals try to exploit the human's element of security and inherently psychological manipulation. In fact, according to a security industry survey, social engineering tops the list of the 10 most popular hacking methods.

Kevin Mitnick coined the term "Social Engineering" which has been repeatedly mentioned in several articles and papers on network and information security. There are various definitions of social engineering and also a number of different models of social engineering attack (Mouton, 2015, 2016).

The process of doing social engineering is known as a social engineering attack. Social engineers target humans with access to information, manipulating them into divulging confidential information or even into carrying out their malicious attacks through influence and persuasion.

Social engineering is deeply entrenched in both computer science and social psychology, knowledge on both disciplines is required to perform an attack.

A trivial example of a social engineering attack is when an attacker wishes to connect to an organisation's network (Mouton, 2016). As a result of his research, the attacker finds out that a help-desk staff member knows the password to the organisation's wireless network. In addition, the attacker gained personal information regarding the staff member who has been identified as the target. The attacker initiates a conversation with the target, using the acquired information to establish trust (in this case the attacker misrepresents himself as an old school acquaintance of the target). The attacker subsequently exploits the established trust by asking permission to use the company's wireless network facility to send an e-mail. The helpdesk attendant is willing to supply the required password to the attacker due to the misrepresentation, and the attacker is able to gain access to the organisation's network and achieve his objective.

The work of Mouton (2016) proposes detailed social engineering attack templates that are derived from real-world social engineering examples. The proposed social engineering attack templates attempt to alleviate the problem of limited documented literature on social engineering attacks by mapping the real-world examples to the social engineering attack framework. Mapping several similar real-world examples to the social engineering attack framework allows one to establish a detailed flow of the attack whilst abstracting subjects and objects.

The attacks of Kevin Mitnick (Mitnick, 2002) showed how devastating sophisticated social engineering attacks are for the information security of both companies and governmental organizations.

Social Network and Security

With the advent of social media and the Internet, social engineering has become easier and more commonplace. The creation of such attacks requires background information on targets. Individuals are increasingly releasing information about themselves online, particularly on social networks. The influx of employees using social media throughout the working environment has presented information security professionals with an extensive array of challenges facing people, process and technology.

The security behind social networks has become stronger in recent years, but relies mostly on the user to do the majority of the work in securing their identity and personal information from the outside world.

Numerous studies have shown that there is a growing correlation between social engineering and social media sites such as Facebook and Twitter, due to the wealth of personal and organisational information to be found within these environments (Furnell, 2008; Sanders, 2009).

More pointed attacks that target a specific person occur on social networks such as Facebook. These types of attacks make up over 39% of all social engineering attacks (Social engineering risks explored, 2011, September 22 from <http://www.continuitycentral.com/news05936.html>). These attacks look to find information on a specific individual to analyze and develop a social engineered attack against that person.

Cyber criminals, also called scammers, take advantage of human dependence on common social trust cues. They have been taking advantage of our human desire for news and social relevance to socially engineer us into giving away vital information.

A trivial example. If something has hundreds of Likes or Shares or if a friend had shared it, people mistakenly think it should be legitimate, people mistakenly think the information should be trustworthy. The scammers know this and they have used this to their advantage. Celebrity news is also always popular, especially fake deaths. While it may seem like an innocent hoax, it could have easily been exploited by cyber criminals to get you to click on a malicious link.

The work of Algarni (2017) aims to investigate the impact of source characteristics on users' susceptibility to social engineering victimization on Facebook. In doing so, we identify source credibility dimensions in terms of social engineering on Facebook, Facebook-based source characteristics that influence users to judge an attacker as per these dimensions, and mediation effects that these dimensions play between Facebook-based source characteristics and susceptibility to social engineering victimization.

Individual vs. Company Threats

Protecting the confidentiality, integrity and availability of information assets is a significant global business challenge for information security. Social engineering tries to manipulate your employees to gain access to valuable company assets. Information on employees of a given target company can be collected in an automated fashion and potentially misused for automated social engineering (Huber, 2010).

Businesses have a difficult job balancing company security and employee freedom on social media. While some business may have strict policies about what can/can't be shared on social networking sites like Facebook or Twitter, others don't have any policies at all.

Practices such as organisational engagement with social media and the publication of employee rosters on organisational websites are enabling attackers to easily identify an organisation's employees from amongst millions of social media users.

Approaches

Social engineering lifecycle try to obtain useful information to execute some successive malicious activity, it is composed of the following steps (Wilcox et al, 2014):

1. **Fact-Finding:** Social engineer tries to gather information that can then be used to build a relationship with the target important to the success of the attack;
2. **Entrustment:** Social engineer may exploit the willingness of a target to be trusting, in order to develop rapport with them;
3. **Manipulation:** The target may be manipulated by the trusted social engineer to reveal information or perform an action;
4. **Execution:** The target completed the task requested by the social engineer.

Phase-Base Model (Algarni, 2017) conceptualizes how the social engineer influences, persuades, and deceives victims. The success of attack is based on how well the social engineer performs the following eight phases:

- **Phase 1:** Using suitable gates of snss to gather information;
- **Phase 2:** Determining the tactic and developing a plan;
- **Phase 3:** Relying on one or more socio-psychological factors;
- **Phase 4:** Using suitable gates of SNSs to reach the victim;
- **Phase 5:** Wearing a suitable hat and playing a suitable character;
- **Phase 6:** Developing trust and a sense of safety;
- **Phase 7:** Choosing the perfect time;
- **Phase 8:** Using professional skills.

Source-Base Model (Algarni, 2017) is related to Phase 1 and Phase 4, in order to specify three sources or gates of threats:

1. Insecure privacy setting;
2. Friendship and connection with strangers;
3. Insecure dealing with content.

Different kind of techniques can be used, in order to obtain personal information using social networking sites, as described in following paragraphs.

App

Some social networking services like Facebook may allow you to add third-party applications based on API provided by social network platform (Srivastava, 2011), including games and quizzes, which provide additional functionality. Social media websites are advanced web applications, as their use requires a high level of interaction and capabilities.

A common form of attack is to entice users to authorize some third-party application, which is then given permission to access the user's personal information, post photos and status update, share link to your timeline or to any group you belong, post on behalf of you on the Facebook pages you own, access your, manage your page (Mayrhofer, 2013).

A study by the University of Virginia cites that out of the top 150 Facebook applications, all of which are externally hosted, 90.7% of applications needed nothing more than publicly available information from members. However, all of these applications were given full access to personal information not necessary for operation but supplied by the user granting the applications' total access to their account (Felt, 2009).

Moreover, Facebook warns that third-party apps could have been affected by recent breach.

It is necessary always beware of what permissions you give to a Facebook third-party application, even though Facebook is reviewing application's permission requests. Don't give permission to an application if you don't trust the website or application.

Data Re-Identification

Data re-identification typically deals with the linkage of datasets without explicit identifiers such as name and address to datasets with explicit identifiers through common attributes (Samarati, 1998). It has been shown that most of the US population can be identified through the combination of ZIP code, birth date and gender (Sweeney, 2000). Most Facebook users provide this information. Social engineers can take their data to estimate what their Social Security Number is.

Emails

One very common conduit for social engineering is scam and phishing emails. The email scam is an unsolicited email that claims the prospect of a bargain or something for nothing. The phishing email is message designed to look authentic and usually imitate format used by the trusted company, including their logo and branding. It will redirect the user to a fake site, that appears like the legitimate, but has a little different URL. In today's highly connected society an individual spends more time on the Internet or communicating by email. Due to large number of emails received, the brain creates routines, which can help deal with and process things more efficiently. But these routines can also compromise the ability to pay attention and to cause the brain to bypass details within the email which would help detect fraudulent content. So, scam and phishing emails can be highly disruptive.

Combination of three taxonomies is most commonly used in phishing (Ferreira, 2015): Cialdini's principles of influence, Gragg's psychological triggers, and Stajano's principles of scams. Principles of persuasion and people's negative emotions that are used in scam messages are defined in the work of Jakobsson (2016), it also describes automated countermeasures based on an understanding of the type of persuasive methods used by scammers.

Email from a friend can be used for attack, taking advantage of curiosity and trust. If a criminal manages to hack or socially engineer one person's email password, they have access to that person's contact list—and because most people use one password everywhere, they probably have access to that person's social networking contacts as well. Once the criminal has that email account under their control, they send emails to all the person's contacts or leave messages on all their friend's social network pages.

Many Facebook users have received phishing e-mails, and many have given the attackers private information such as login and password. An example of suspicious phishing e-mail:

Email subject: Your Facebook account has been blocked temporarily.

Dear Mister,

Your Facebook account has been blocked temporarily. It usually means that we need some more information about your account. Activate your account so we can confirm that you own the account

What do I have to do?

To activate your account, just click on this link and confirm your information. (It only takes a minute.)

Let's take a look at it in a bit more detail:

- email has not come from Facebook, because email address is different;
- spoof address used to make it look like someone else is using your account;
- some links lead to genuine Facebook pages;
- some links lead to a fake page to input your login details.

Without casting a sceptical eye over it, you might find yourself taking the information at face value.

Most email filters use techniques to identify email keywords, grammatical inconsistencies, typos or information misplacement. These can help email filters to have a wider range of detection but can also provide for many false positives since typos and inconsistencies are also frequent in legitimate human-written emails while with automatically generated emails, it may depend if the used template has mistakes or not.

However, the mentioned methods are effective only against the types of messages for which they were designed. Scammers are continuously changing the content of their emails to defeat these approaches, and their new content will not be recognized until the new signature is integrated within the filtering mechanisms. Scammers have increasingly come to realize that by cleverly targeting their victims, they can achieve even better returns. Thus, these prevention methods tend always to be one step behind the scammers.

To address this problem, it is necessary to widen the identification of scam emails through scrutinizing the persuasive content rather than just evaluating the form and structure. One approach to persuasion used by scammers involves the use of meaningful contextual information such as victims' online shopping or banking preferences, to make scam emails seem more appealing and trustworthy. Other persuasive elements such as logos, graphics, colors, or words and phrases that are recognizable by the recipients, can be employed to make dishonest emails appear legitimate and even personal.

False Friends

Social engineers can abuse the overall community trust by using the psychological deception of starting a friendship with the victim in order to build trust between the attacker and the victim. The main goal of any social engineer is to manipulate this trust to launch a premeditated attack. This is a simple and effective approach, because a third of social media users regularly accept unknown, unsolicited requests.

Most people when asked will agree that not everyone they know is their best friend; there are the mere acquaintances all the way to those with whom we share our deepest secrets, along with many shades in between.

Social networking sites has added new meaning to friends: two people are often friends or not friends. One may have a couple of close friends and thousands of distant friends, a social network may simply categorize them all as friends, but there are the mere acquaintances all the way to those with whom we share our deepest secrets, along with many shades in between.

There are two categories of malicious profiles or fake users. Minimally Invested Profiles are designed to target users who readily accept requests without doing any manual analysis of a profile, the social engineer will fill out the fields necessary to appear legitimate in a friend or connection request: name, picture, job title, and location;

Fully Invested Profiles are a more robust profile that is designed to fool just about anyone, the social engineer can spend considerable time filling out as much of the profile as possible, gathering connections to appear legitimate, and taking time refining and editing the profile to pass a basic screening.

More friends aren't necessarily a bad thing. The problem is who has access to our information? Social networking sites provide a certain level of access control, but most people do not take the effort to configure these properly. Therefore, everyone ends up with equal access rights to our information. It is necessary to consider that sometime information travels through several networks of friends, therefore it is possible that bad guys ends up with equal access rights.

Malware

Attacking a target with malware is easier than ever. Cyber attackers don't need to be computer programmers anymore, they can buy their malware on the dark web. A lot of the malware for sale is spyware like keyloggers and RATs (remote access Trojans).

Malware can then be hidden in file such as a photo, an audio file, or a document. The target won't see an executable filename, but an innocuous media filename, if the target views the photo, listens to the audio, or opens the document, the malware will execute on their PC or smartphone.

Malware on Facebook can take many different forms, but it most often manifests as a link being promoted or sent via Messenger to convince the user to click on a link that invisibly installs some malware. The main iterations of malware include the following:

- a friend ambiguously promoting a product or a service
- a message from a friend with a link or a video and a phrase such as "Is this you?" or similar
- any promotion, post, or message from a friend which seems dissonant with their tone or usual social media practices.

Automated Attack

Classic social engineering attacks are expensive, due to the fact that building and maintaining rapport with someone to finally exploit the relationship is a time-consuming task. The ultimate goal of automation is to reduce the human intervention time to a minimum.

Social Media can be evaluated as communication platform, by offering services such as private messaging and chats which can be used by automated social engineering bots. Automated social engineering bots require little human time resources, are scalable and thus make social engineering a cheap and promising attack (Huber, 2009).

The work of Huber (2009) introduces a high-level description of a possible software application for automated social engineering, using the attack segment of the cycle of deception as a framework based on automated social engineering (ASE) attack cycle.

OSINT TOOLS

The effectiveness of social engineering attacks can be greatly increased using Open Source INTelligence (OSINT) to boost the effectiveness of the deceptive ploys delivered in an attack (Jagatic et al., 2007).

A malicious user is perfectly capable of utilizing Facebook's advanced search function and cross reference user to gain access to hidden portions of a user's profile.

Simply Googling the company name with function such as `site:Facebook.com` or `site:Linkedin.com` or `site:Twitter.com`, employee names, products and commercial information can be found, and digging gradually deeper yields a mountain of information. In similar way, it is useful to search on Google the user social account.

Maltego is made by Paterva <https://www.paterva.com> and is a powerful tool to gather, combine and analyze OSINT on a target. Maltego provides a way to import or add data. It also provides transforms that can gather additional data using electronic methods.

Social Network Analysis

Social network analysis is a mathematical technique developed in modern sociology, in order to understand structure and behavior, to map relationships between individuals in social network, to study information flows.

The work of Vasconcelos (2013) deals with the possibility of social engineering attacks using footprinting performed through Social Network Analysis. Experiments were carried out using a Facebook user account. Various graph layout algorithms were studied and results with Fruchterman Reingold algorithm are demonstrated in this paper. An test user account was analyzed and graphs of the social network were produced allowing understand the group formation and behavior of actors in social networks, as well as information flow.

Proposed Solutions

The one mistake companies make that leaves them vulnerable to phishing attacks is not having the right tools in place and failing to train employees on their role in information security.

It is possible to harden yourself and your organization against social engineering attacks with education and by encouraging a healthy sense of skepticism, by spending some time reviewing a social network's privacy policy and understanding the default settings for your account.

The way to prevent attackers from acquiring false friend is to avoid people you don't personally know, even if they are friends of known friends, to require identity checks both online and in person to verify that a person is who they say they are, to avoid posting enough information on Facebook for false friends to be able to track you and know where you are and what you are doing all of the time.

Some huge red flags for recognizing a social engineering attack:

- Unsolicited call from someone claiming to be tech support;
- False urgency requests, don't fall for 'Act Now!';
- Fear can be a powerful motivator, don't fall for 'Help Me, I'm your friend and I'm going to be mad'.

Relevant ways to protect yourself are:

- Delete any request for financial information or passwords;
- Reject requests for help or offers of help;
- In email software set spam filters to high;
- Install anti-virus software, firewalls, email filters and keep these up to date;
- Set operating system to automatically update;
- Pays attention to the kinds of personal data they share on social media
- Frequent change of password, so hackers are not able to spoil account;
- Perform a regular backup to an external hard drive or the cloud, after backing up, disconnect drive to avoid malware to encrypt the backup drive as well;
- Social platforms give the user authority to control their privacy, by regulating privacy settings that display personal information.

Moreover, related to password, it is suggested to write your secret questions to wrong predictable answers. In this way, if a secret question what's your dog, you should not to write your dog real name, write only different answer like "thisissmysecretanswer". If you share your dog name, this protection saves your passwords.

In specific case of company threats, company culture based on security compliance and legal aspects is the best defense against social engineering scam, therefore it is recommended to:

- Establish social media policies and guidelines, regarding how social media participation will be applied to all of the members of an organization;
- Never post business information without permission, such as work schedule or photographs taken in the office;
- Increase employee awareness of the many tricks employed by social engineers against them in the workplace;
- Alerting employees to the high costs involved with brand and reputation damage;
- An endpoint protection system that can block the latest malware is, probably, best bet at stopping the attack.

Humans need to be trained, they are the weakest link. Companies should employ a training geared towards each kind of user, so that everyone is aware of the latest attacks. Employees should be tested by having an outside party conduct a social engineering test. These kinds of tests help keep the employee on their toes and more likely to avoid the attacks.

ETHICS IN SOCIAL ENGINEERING RESEARCH

Ethics is the study of morality. By providing principles and theories about different viewpoints about what is meant to be ‘right’, ethics helps classify arguments, defend a position or better understand the position others take and, in doing so, helps determine an appropriate course of action.

White hat hackers are knowledgeable individuals whose primary job is to understand a system from the inside out and this includes both the hardware and software sides of a system. These ethically certified hackers are instrumental in probing hardware and software systems for weaknesses. The tests that white hat hackers perform assess both computer system weaknesses as well as weaknesses in a business’ corporate IT policy.

Social engineering techniques are ordinarily performed on human participants, therefore it is necessary to think about the consequences of a variety of situations, ranging from agreeing the parameters of a test, to deciding which techniques should or should not be allowed during a test. In this way, the ethical impact on these participants needs to be considered, to ensure that harm does not befall those who participate in such research.

The work of Mouton (2015) identifies a number of concerns regarding social engineering in public communication, penetration testing and social engineering research. It also discusses the identified concerns with regard to three different normative ethics approaches (virtue ethics, utilitarianism and deontology) and provides their corresponding ethical perspectives as well as practical examples of where these formalised ethical concerns for social engineering research can be beneficial.

FUTURE RESEARCH DIRECTIONS

Defense strategies against automated social engineering attacks are a necessity and could form another cornerstone for future research. It is possible to study and design countermeasures which can be better equipped to target and minimize the success of specific types of attacks. The security measures of social networking sites are primarily concerned with unsolicited bulk messages. Emphasis must be given to new cyber education and awareness of users.

CONCLUSION

Social engineering has become a popular form of obtaining and utilizing confidential information in virtual communities and it is a fundamental step in various attacks to information systems. This chapter tried to bring some clarity to the different types of social engineering based on social networking sites.

Anyone in today’s modern world is vulnerable to social engineering and thus must remain constantly aware of who they interact with both online and in person, so it’s important to recognize an attack in progress and respond to it appropriately.

The problem is that, combined with social media, information harvested is easy to process and social engineering scams become increasingly more difficult to spot, because they’re coming from seemingly trusted sources: friends, professional references, and even family.

End users don’t understand that oversharing on social network channels can compromise more than their reputation.

To combat these new security threats, businesses need to apply new policies to protect their users and their information. To effectively guard against social engineering attacks, organisations must go beyond awareness initiatives and help end users actually make good security decisions and improve their cyber-hygiene using social networking sites, therefore cyber education is the key to success.

KEY TERMS AND DEFINITIONS

API: Application programmin interface, a set of subroutine definitions, communication protocols, and tools for building software.

Social: Engineer: A person who is expert on the social engineering techniques, he uses deception to manipulate individuals into divulging confidential or personal information that may be used for fraudulent purposes.

Social Engineering Attack: Various manipulation techniques to elicit sensitive information, manipulating a person into giving information to the social engineer.

Social Network: A social structure composed of individuals, organizations, company, etc. that are connected by relationships and interactions.

Social Network Security: The process of analyzing dynamic social network data in order to protect against security and business threats.

Social Networking Site: An online platform that allows users to create a public profile and interact with other users on the website.

Third-Party Applications: An application that is provided by a vendor other than the manufacturer.

User Account: An established technique for connecting a user and an information service.

Social Media and Identity Theft Implications on Nigerian Victims and International Economy

INTRODUCTION

In this 21st century and beyond, many can attest to the role of ICT in the development of communication in the world. According to Adaja and Ayodele (2013 p. 65), ‘one of the developments in Information and Communication Technology in the 21st century was the finding and advent of the new media which have enabled the formation of several channels of social communication.’

As a result of the fast-growing technology, in social communication, there has been dependence on the internet by a large percentage of individuals around the world.

Consequently, personal information is shared when creating profiles on social media platforms thereby making it easy for online crimes to take place. Security attacks such as hacking, identity theft, phishing scams, viruses are now common online as users share their names, date of birth, the name of schools, family information, and others on social media sites.

While activities online increase, there are concerns about the ways personal information shared by social media users may be collected and analysed (Hinduja and Patchin, 2009). According to Walker (2016) the state of the net poses, that more than half of the people using social media applications share private information about themselves online, exposing themselves to online dangers. The findings reveal that: 25% of persons with a *Facebook* account do not use the site’s privacy control or are not aware of them, 40% of social media users post their personal identity information online, exposing them to identity theft and 9% of social media users dealt with a form of abuse within the past year (e.g., malware, online scams, identity theft or harassment) (Finch, 2003).

Due to this increase, there seems to be a connection between the usages of such media with identity theft, cyberbullying, online sexual predators mainly affected youths because of lack of security consciousness and privacy about personal information (Jegade, et, al; (2016) McGillivray, 2015). Also,

DOI: 10.4018/978-1-5225-9715-5.ch055

committing identity fraud with the help of the Internet may be more accessible and more efficient for criminals than ever before (Milne et al, 2004).

Emily Finch, the author of “What a Tangled Web We Weave: Identity Theft and the Internet,” believes that social media users are “less security-minded about their personal information when they are online than they are in ‘real life’ situations.” This is true because when people are on social media sites, they reveal information online that they would not show to someone in real life situation. It is therefore easy to understand how this information is wrongly used and leads to identity theft (Finch, 2003).

Identity theft did not begin over the Internet. Before the use of internet became popular, fraudsters stole people’s identities by going through their documents. They also used their mobile devices to commit such fraud. In Nigeria, before the prominence of the internet, there were fraudsters commonly called 419’ers, and these fraudsters duped mostly big men and women who lived in Lagos (Ezea, 2017).

With the acceptance of internet, identity theft is becoming more popular around the world. According to Federal Trade Commission, identity theft was the number one fraud in 2008. Now with its popularity, different online fraudulent activities have become the norm over the years.

However, Nigeria social media users continue to fall, a victim of this fraudulent activities, as they continue to imbibe the culture of registration and to use newly established social media network with more existing features (Omodunbi et al., 2016)

Therefore, diverse investigation abounds on the issue of social media identity theft. Selwyn (2004) examined how older adult employed the uses of social media to lower perceived life stress thereby making them victims of social media identity theft. On the other hand, Rezmik (2013) investigates the dominant methods used in carrying out social media identity theft on social media networking site. They further stress the need for the Federal Governments to be solely responsible for the protection of social media users by ensuring the perpetrators are punished (Al-Daraish et al., 2014). Most importantly, Milne et al., (2004) discussed online behaviours that lead to identity theft to create awareness for online security for social media users.

To this end, Kayode-Adedeji et al., (2017) emphasized the need for regulating the social media, while Adu et al., (2014) further reviewed the different security and privacy risk threatening online social network users and proposed several systems that enable internet users’ activities to be monitored. Little research, however, has been done on the implication and users’ awareness of the necessary security measures social media users can put in place to avoid being a victim of social media identity theft.

Considering the differences that exist in countries, regarding the culture of communication on social media, the results emanating from this investigation gives a future opportunity for a comparative study serving as a guideline or map in the development of policies for future cybersecurity as emphasised by Peters (2017).

So, this research attempts to find out the implications of this crime on the victims, to ascertain if people are aware of this crime, to educate people on avoiding social media identity theft and also the reasons for such fraud.

ICT IN THE PRESENT AGE

Information and Communication Technology (ICT) inventions on the cyberspace remains over-whelming as more platforms are created to allow for diverse activities. There has also been applications (Apps), and websites, enhanced by new features on already existing internet environment. Communication technology has allowed the use of social media platforms, new features on gadgets, solar-powered drones,

apps, wireless routers LED (Li-Fi), and so on. Most of these above mentioned inventions and platforms increased the benefits the cyberspace already generates, making communication easier by providing people from different fields, with a more convenient approach of achieving task.

However, as the internet brings more advantages to user, some embrace these innovations for fraudulent activities and cybercrimes such as; cracking, software piracy, ponography, ATM fraud, *Yahoo-Yahoo* extortion, Identity theft, phishing which begins with fraudsters engineering applications and internet platforms for manipulation of users for unlawful gains. The Nigeria Cyber Security Report (2017) records that the desperate actions employed by fraudsters have resulted in the increase of cybercrime by 35 per cent between 2016 and 2017.

Nigeria presently lacks a working cybersecurity law. Maintain, O. Ogunleye, S. Ayinde, S. and Ad-ekunle, Y. (2013) from their research discovered that the rise in cybercrime in Nigeria has influenced drug trafficking, affected Nigerians image negatively, and encouraged plagiarism and infringement.

In light of the above stated information and implications, the book chapter seeks to address one of the major prevalent cybercrimes known as 'Identity theft', which involves the use of another person's identity to commit crime online. The chapter titled; 'Social media identity theft: The implications on victims in Nigeria' will be conducted with the sole aim of examining the implications of social media identity theft on victims and level of awareness on security measures on social networking platforms. In order to achieve these aims, the chapter engaged the knowledge of professional in the field of internet security such as programmers to provide original content on the recent methods employed by fraudsters in stealing others users' identity for fraudulent purposes. Victims of social media identity theft were interviewed from Nigeria to further understand their experiences, to educate other internet users for possible future attacks. Authors would be from relevant field namely: computer scientists, media communication, and criminology and security studies respectively.

The examination of the above areas of cybercrime, prepares internet users, ICT empowered organisations, and other Nigerian organisations who mainly engage the use of ICT, to defend themselves from internet attacks.

The results from the analysis could help reduce the negative effects on the dwindling Nigerian economy. The development of the internet and ICT will endure; therefore, it becomes imperative for computer programmers, social media platform providers and regulatory bodies that presently exist in few states in Nigeria to seek out ways to tackle problems that could be generated from online usage by online users. The results from the study is useful because it will encourage internet users to provide information online in cases of e-commerce because internet banking and transactions encourage international trade, therefore results from this study is useful. This will further drive necessary bodies, governments and organisation to begin to put in place necessary measure in curbing the act of identity theft and 'Catfishing' online.

History of Social Networking Sites

Things began to change rapidly in the 20th century as a result of the development of ICT. After the first supercomputers were created in the 1940's, scientists and engineers began to develop new ways to build networks of interconnectedness between the computers and these new ways led to the birth of the internet which we have today (Hendricks, 2013). CompuServe was the earliest form of Internet developed in the 1960's and also old forms of electronic mails were produced during this time. Communication via letters gradually became olden, as the networking technology during the 1970's improved with the invention of Usenet, which allowed users communicate through a virtual newsletter (Hendricks, 2013).

The first social media site was referred to as Six Degrees, and it was created in 1997. This social media site was conceptualized after the six degrees of separation theory, and it allowed users to create a profile and then become friends with other users who were registered on the site. It lasted from 1997 to 2001 (Hale, 2015). After the era of Six Degrees, the Internet transcended into blogging and instant messaging. Although, blogging was not a direct mode of social media communication, it allowed people to read articles and share opinions by commenting on such article. The term 'blog' was originated from weblog, and Jorn Barger coined it.

As the Internet became popular, more social media sites were developed. A social media site called Myspace became famous in 2003. Its main purpose was to connect people to become friends. Then, *LinkedIn* was developed, but it was geared towards a more professional setting that allowed different people from various walks of life to network and creates contacts for business purposes (Hale, 2015).

In 2004, Mark Zuckerberg developed *Facebook* as a Harvard student. According to a statistical report by Africa Internet statistics in June 2017, the number of *Facebook* subscribers in Africa was 1,979,703,530 billion. Then in 2006, *Twitter* was created by Jack Dorsey, Biz Stone, Noah Glass and Evan Williams. It allows users to send tweets and also send messages to their various followers. After the creation of *Facebook*, *Twitter* and some other social media sites became prominent with the same functions while few social media sites had little features that made them distinct. Social media sites like *Flickr*, *Photobucket*, *Instagram*, and *Snapchat* provide features that distinctively allow users to share pictures, and also allows users to chat with their friends around the world.

Tumblr was introduced in 2007 by David Karp, and it was a microblogging site, and also it allowed users to communicate with one another while sharing articles, pictures, videos that were of interest to the users. *Yahoo* was developed in the late 2000's, and it later bought *Tumblr*. Other social media sites that have taken over the social space over the years are *Blippy*, *Loopt*, *Groupon*, *Buzz*, *Google*, and many others. As a result of the fast-growing fame of social media platforms, people started using these sites as a form of advertising businesses. So, social media platforms were not only for users to communicate with one another but also business owners used social media platforms as a marketing and advertising platforms.

Today, there are thousands of social media platforms that have taken over the social space, and these platforms help in communication and have specific features that make them distinct from one another.

The Nature of Social Networking Sites

Social networking sites are internet or mobile-based social space that allows people to connect, communicate, create and share content with others. People engage social media to interact with friends, family, organizations, and the world. It enables people to send instant messages, find friends, join online groups, and share photos, videos, opinions, articles, web information, stories, and more.' These actions explain the automatic freedom social media gives to users to create their profile pages and share contents.

Stutzman (2007) opines that there are various types of social networking sites. They are divided into two. Some sites-based solely on the users' profile and information and the other focus exclusively on users building their content.

The profile based social networking sites are built and organized around users' profile pages. *Facebook*, *Myspace* are perfect examples of this type of sites. Users enhance their pages in different ways and also contribute to another users' page.

In the content-based sites, a user's profile page is an essential means of organizing relationships and networks but also is vital to the way a user posts content on social networking sites. *Instagram*, *YouTube*, and *Snapchat* are good examples here because relationships are based on the people who comment on videos or pictures a user upload.

The social media space is developing rapidly, as people around the world are being acquainted with the way social media operates and functions. Social media networks give users the room to manage and build networks of friends via the Internet, and these friends can be individuals, businesses, events and other things. However, it primarily enables one to build an online network base and keep in daily contact with these created networks. Social media networks allow users to freely add anyone as a friend, or some friends have to be made on request in which the two parties have to acknowledge the fact that they know each other.

Permission is an important feature of most Social networking sites. It allows members and groups to control who gets access to their profiles, information, connections and spaces. This setting allows users to keep information private, or to make information public. Through these combinations of permissions and privacy, users can manage a range of different relationships online, as well as managing their online presence.

Another important feature that all social media network sites have is the friend request or follower request feature. Security measures on social media networks differ from status to status, although basic security measures are enabled by social media platforms. There are settings that allows users to keep personal information private and it is only visible to friends on the user's contact list and can even restrict information to some particular friends. Through security settings, users are able to control the way they handle relationships online via social media networks, and their online presence.

Social networking sites also differ based on the functions they provide to the users. Generally, they are used for communicating but each media still has its distinct function(s). According to Boyd and Ellison (2006), Social networking sites have three common elements: a member profile, the ability to add friends or people to a contact list and supported interaction between members of the contact list.

Impact of Social Networking Sites on Users

The different Social networking sites have made impacts on communication, social cohesion, community engagement, business, social relations, crisis management and a whole lot more. These impacts vary from good to bad. Social networking has become a part of the daily life experience for an increasingly number of people. (Gemmil, and Peterson, 2006). Social media is the environment in which social networking takes place and has altered the way consumers gather information and make buying decisions.

Beebe, Beebe, and Redmond (2005) reveals that conversation between family members have being altered by technology. Social networking sites being a part of the internet has altered the world of communication by helping users communicate timely, accurately in clear messages. The Social networking sites has evolved from sharing information, pictures or videos to interacting, engaging and networking. The fact that the social networking sites has altered the means of communication does not leave the terrestrial medium of communication useless. Rather it has allowed real time broadcast and has aided citizen journalism by enhancing free flow of information, eyewitness account and freedom of information. The change in communication by social networking sites have revealed the applicability of social networks in everyday life.

Almost 4.2 billion individuals connect to social networking sites via their mobile devices and this shows that the social networking sites are relevant to people differently. The sites have made it possible to develop social relations with people of similar interests and connect people across the globe without any geographic, economics or political barriers. As identified by Kaplan and Haenlein (2010), the basic keys to social media success are user participation and user interaction. Weinberg and Pehlivan, (2011) also reveals that people with different backgrounds can engage in long-term discussion because social networking sites reflect views, richer conversation and long-term engagement. With this said, Social Networking Site (SNS) is a process of becoming more acquainted with people, encourages long-term relationship and help to strengthen communication among families, business partners and even friends. However, as much as SNS have positively influenced social cohesion, it may also bring an unpleasant experience on online behavior as people have the tendency to behave differently based on the person they are sharing information with. In the process of social relations with people (strangers) Social media users are susceptible to social vices such as cybercrimes, cyber bullying, pornography and some are even impersonated as they tend to share information about themselves to strangers they meet online. Adolescents especially are easily influenced by what they see on SNS most especially the perception of how other people live their lives making them feel inferior and also start believing that other people have better lives than they do.

Furthermore, as people most especially teenagers join SNS to keep up with their social Life, adults and organization especially use the platforms to promote their business and brands since SNS gives opportunity for cheap advertisement. Social networking has positively and negatively impact buying and selling has most business is known through the social media platforms. SNS like Facebook and Instagram have a different platform for businesses where organizations can upload contents about their businesses and sponsor those contents to a particular number of people who are likely to patronize their services. Business with SNS are likely to attain successful results compared to business without social media platforms. So, while the customers (social media users) move with the trend, organizations also make the shift as their customers are easily available on the platform. As much as SNS is used to promote businesses, it has also helped organizations to manage crisis and misunderstanding. Freberg (2012) in his study stated that the viral spread of information on social media could be viewed as an advantage to a crisis professional who must reach the public as quickly as possible. However, social networking sites can only have great impact on business if the right audience is targeted and reached.

As much as SNS has encouraged E-commerce, E-banking and E-governance, it has also negatively affected some business. Some business profiles have been hacked, some are impersonated by fraudsters who make followers believe it is the original platform and then making them pay for a product without getting the delivery.

Social networking sites has revolutionized our ability to connect and collaborate in ways we could not have fathomed five years ago. Students, businessmen and all other professionals can collaborate through web 2.0 as well as social networking sites. Students' collaboration could be used to aid the process of working with others. Students can post ideas through instant messaging like *WhatsApp*, *Gmail* and get feedback from whom they are working with. They can also brainstorm to narrow or expand concepts. They can discuss ideas, share ideas and collaborate on a project. An example is research clusters. They can always have their meeting on the SNS platform. Programmes and discussion are also done through the social media platforms like *WhatsApp* where you have discussion programme with a fixed time.

Through Social Media, virtual proximity has become a substitute of physical proximity in the case of standard transactions. Generally speaking, network externalities appear when the last person connected to the network, due to his/her participation, ensures the increase in utility for all the users. Content creators, such as teachers, can place special interest in creating positive interactions between their target audience and social networks to improve their attitude towards media. Such highly involved interactions between users ideally create positive experiences toward learning.

Social Media Identity Theft in Nigeria

Identity theft occurs when an individual, a perpetrator uses another person's information for illegal purposes. Identity theft takes various forms like financial, criminal and medical identity theft. Financial identity theft includes activities that tamper with one's credit card information. Criminal identity theft is used to commit crimes in another person's name and to carry out financial crimes in another person's name. (Michael et al., 2014). Social media identity theft is a form of cybercrime in Nigeria, although most research have not documented the level of its existence.

Fraudsters obtain people's information through an act called dumpster diving. Important documents may include bank statements, receipts, NEPA bills, ATM card papers, and many more. When these documents are retrieved, vital information such as: date of birth, full name, mother's maiden name, ATM pins, passwords, driver license numbers amongst others.

In Nigeria, Social networking sites have reached a high mark such that every sector including banks, organizations, business owners, schools, government, use these sites to promote business and communicate with the public. Social networking sites like *Facebook*, *Twitter*, *Snapchat*, *Instagram* and others serve as a platform through which fraudsters engage in such fraudulent activities. There are many reasons associated with people would becoming fraudsters on Social networking sites, and they include: unemployment, yearn for more money, the absence of efficient cyber laws in the country, and Lack of security measures put in place by individuals on computers and many more.

Identity theft in Nigeria ordinarily started with '419,' which was a popular form used by fraudsters to collect money from unassuming victims. This is carried out in a way that the fraudsters would pretend to be people who they are not and thereby swindle the victims unknowingly. Today, social media identity theft occurs on social media platforms like *Twitter*, *Facebook*, *Instagram*, *WhatsApp*, *Snapchat*, *LinkedIn*, *IMO*, and others (Michael et al., 2014).

With the advancement of technology, especially in the area concerning the internet, new ways to steal people's identity keep springing up and it is becoming harder by the day to actually stay secure and protect personal information. The use of social media platforms in Nigeria is still a growing phase and therefore a lot of persons are apathetic about the risks that come with sharing some sorts of information including pictures and videos online (Rezmik, 2013). It is important for people to be aware of security checks and measures to take note of when creating user accounts on Social networking sites. Some of these measures include:

Creating strong passwords: when creating an account on a social media-networking site, it is important to ensure such passwords do not contain information about you. They should contain capital letters, small letters, symbols, and numbers. Passwords should be changed from time to time and kept away from the public.

Table 1. Implications of social media identity theft

RESPONSE CATEGORIES	PERCENTAGE (%)
Loss of Social Media Account	47.1
Financial Implications	18.1
Loss of Friends Contact Online	21.0
None That I Know Of	13.3 n= 210

Secondly, give minimum information when filling out forms online to create accounts on Social networking sites, not all fields are necessary to fill. Social media users are also encouraged to be careful about what pictures, videos, and information they post on their status and use privacy settings. There should be a regular check on google to trace any forged accounts that may be operating with one's details and avoid accepting friend requests from strangers.

METHOD

The qualitative and quantitative research design was adopted. Interview and questionnaire were used as a method to gather data for the study. A total of 210 victims of identity theft completed a copy each of the questionnaire. Also, for the qualitative data, a focus group discussion consisting of 3 male and 3 female victims of social media identity theft were interviewed. A programmer was also interviewed to further examine diverse methods used by perpetrators to carry out social media identity theft.

The Uses and Gratification Theory

This theory was propounded by Elihu Katz in 1970 which states that the audience use the mass media to satisfy their certain needs (Onwubere, 2004). This means that the audience are not participatory individuals of the media, so they select the media messages that satisfy their needs, wants and gratify them.

According to Severin and Tankard (1987), different people can use the same mass communication message for different purposes. The Uses and Gratification theory is relevant in this research because this theory explains how persons use social networking sites to gratify their communication needs and wants. In the case of this study, fraudsters use other people's identity especially on social media sites to satisfy their needs ranging from financial benefits, stalking and to embarrass others.

Social networking sites provide its users a wide option of communication channels either through texting, video calls, audio calls and many more and it beats the issue of geographical barrier, so its users are always online to connect with people from around the world or for other purposes. This makes the availability of improved information to users all the time. This theory is relevant to examine how users make use of social networking sites to gratify their needs but also doing so at their own security cost.

Results

The table above shows that 47.1% are of the opinion that the implications of social media identity theft leads to loss of social media account, 18.1% are of the opinion that the implication leads to financial implications, 21.0% are of the opinion that the implications of social media identity theft leads to loss of friends contact online, while 13.3% are not sure of the implications of social media identity theft on them.

According to the table above, the implications of social media, identity theft mostly leads to loss of social media accounts. The other implications of social media identity theft are financial implications, loss of friends contact online. These implications could mean that the original owner of the account may not be interested in using the account again if necessary actions are not taken, by the social media platform providers. From the focus group interview conducted, it was observed that most of the participants were either embarrassed or sad when they realized that they had fallen victim of social media identity theft. Most people who are victims of social media identity theft, do not realize initially that they have fallen victim at times until their attention is drawn to whatever activity their page is being used for.

According to respondent A:

Okay, I saw a post that was not mine.... It was a nude picture of Kim Kardashian that was posted... My family started asking me if I had gone on the dark side because of the nude pictures, and they started asking me what I was doing, what I was uploading and my religion was questioned at that time.

Also, according to respondent B:

I was devastated and angry. Yes, I lost the account and I was angry. I lost a lot of friends and I kept thinking of how to upload pictures and also how to retrieve the ones I had uploaded in the past. I also had to open another account and that was stressful.

According to respondent C:

My friend told me about it and I reported after which, the account was blocked, but I had to create a new account and it was stressful. I had to start sending friend requests all over again but now I am back where I was as at the time my identity was stolen.

Also, according to respondent D,

The implication was devastating. As with my snapchat, I could not recover the account, I lost my friends and contacts online, but I have gotten over it.

Different Ways in Which Social Media Identity Theft is Carried Out?

The result shows that there are various methods like phishing, forgery, social engineering, phishing sites, pop-ups, and others. Phishing according to one of the respondent A:

Table 2. Respondents awareness of security measures on social networking sites

Response	Percentage (%)
Yes	65.7
No	27.1
Not Sure	7.2 n= 210

... and here, people send mails to people and it is really going on in Nigeria now whereby you see messages in your emails, text messages on your phone, telling you that they want to get information about your bank details. So, phishing is just emails and messages sent to you pretending to be an official company or an official site trying to get vital information from you and some people fall victims of such tricks.

In this case, the possible victim sees messages in their emails, messages on their phones requesting for some information or personal information, such as bank details.

So, pop-ups do not really have to request for information from the target, rather it comes in form of dialogue boxes and once it is clicked on it downloads information from the device and such information becomes used by the perpetrator. According to respondent B,

Perpetrators can just create pop-ups...Some are not adverts, some are actually meant to infect your system when you click on it like when you click on the site, you see something different from the original site, and during that time something has downloaded into your system, and at times you see the thing downloading but when you open the download and see nothing you think it is actually nothing and you leave it that way, but something is in the system and it is till when you use anti-virus that it removes.

Social engineering as a method operates on online forums, blogs, online communities and so much more. It is done on any platform that generates a lot of comments from its users. According to respondent B,

Social engineering is making use of social platforms, basically things that people communicate with, anything that is social and anything that plenty people make use of to communicate with each other and to pass information online like forums too.

Phishing sites are fake sites that look like the original site and a user is not aware of the difference and then puts all of his or her information without knowing that it is the fake site of the original site and through this way perpetrators or fraudsters can illegally gain access to a person's personal information. Phishing sites according to respondent A, is

...these sites pretend to be clone sites of an original site...So, the cloning site would ask for a lot of details and they store these details. The one that is common in Nigeria is the banking way, the fraudsters send sms to your phones informing one that his or her BVN number is wrong so send your details, or that his or her ATM card has issues and sometimes it is also done through emails too. So, you visit this site thinking you are on the real site whereas it is a clone.

Table 3. Respondents' Security Measures on Social Media Identity Theft

RESPONSE	PERCENTAGE (%)
Privacy Settings	73.8
Rejecting Requests from Strangers	7.1
Minimize Basic Information About Yourself	5.2 n= 210

A high number (65.7%) of respondents are aware of security measures on social networking sites, 27.1% respondents are not aware of security measures on social networking sites, while 7.2% are not sure if security measures exist on social networking sites.

According to the table above, most respondents are aware of security measures on social networking sites, and according to the table below, most respondents are more aware of privacy settings as a security measure.

A total of 73.8% of the respondents are more aware of privacy settings as a security measure, 7.1% respondents are of the opinion that not accepting requests from strangers is a security measure, while 5.2% are of the opinion that not putting any basic information about yourself is also a security measure.

Some other security measures include, not accepting requests from strangers, not putting any basic information about yourself, not posting pictures, videos or chatting with friends.

From the interview session, according to respondent A,

But once you accept someone as your friend, they can view anything you post. So, privacy settings are not a form of security against people who are trying to steal your identity they are just privacy settings so, most of these sites what they think of first is their money before any other thing.

Most people are aware of these privacy settings but not a lot of people actually use these settings on their social networking pages. Most people are mostly used to changing passwords if they do not close down the account or lose the account. According to respondent A in the interview session:

So, we tell people to use strong passwords, do not use the same email on your social media page because if you have your email with your social media they can hack your page and also hack your email too using the same password.

According to respondent B, from the focus group interview;

I have not done anything so serious apart from changing passwords.

Also, according to respondent A,

Well me I also do the same thing of changing my passwords, but I change my passwords every week.

CONCLUSION AND RECOMMENDATIONS

This research is titled “Social media identity theft: The implications on victims in Nigeria” and the topic was inspired by the increasing rate of identity theft on social media, i.e. Social networking sites. Most people refer to it as hacking, and they mean more or less the same thing but social media identity theft is more technical and it encapsulates the exact activity that is associated with it. The main purpose of this study is to examine the various implications victims face, implications and security measure adopted as a result of this fraudulent activity. It can be gathered from the research that social media promotes identity theft and its implications on victims are more negative than positive. From the different methods used for this study, one primary thing observed is that the stringent security measures expected to be present on these social networking sites are not as useful as they are supposed to. There are security measures like privacy settings but according to an expert this type of security measure is not effective and it still leaves users prone to online danger like social media identity theft.

One of the experts who was interviewed is of the opinion that most social media sites do not care about the security of their users but rather they are more concerned with how much profit they make from the users in any way. According to the respondent A,

“...most of these sites what they think of first is their money before anything other thing. There is something I read about a guy whose Facebook account was cloned, whereas he had previously shut down the Facebook account and he found out later that the same page he shut down was somehow active still bearing his pictures, information and all, so someone already stole his identity. What actually happened is that when you request for your Facebook account to be shut down, it goes through a process for like a week so it does not shut down immediately. During that week process if you try to send a message or activate the page again, it is going to stop the process of shutting it down so the page will still remain active. And this happened in U.S and the victim said he contacted Facebook and even sent them emails and they told him that their support service will get to it and all, and nothing happened till he contacted the FBI, and told them everything about it and then few hours later the page was shut down.”

Apparently, social media identity theft is common on *Instagram*, a social media networking commonly used. Therefore, avid social media users should be able to determine and control the information to share and with whom such information is shared with. Users of social networking sites should also learn to use strong passwords on their accounts and be careful whom and which sites they share their passwords with to avoid being victims of social media identity theft. It is important for the government to provide security measures in order to protect the citizens against such fraudulent activity in the future by punishing perpetrators. Lastly, social networking site providers should be actively involved by making sure their social platforms are updated to ensure future safety, provide a platform to educate citizens on the importance of online security and how to stay safe in today’s world.

INTRODUCTION

Online phishing is a common form of criminal attempt via fraudulent emails, web links and websites to trick online users to surrender sensitive private information, including user names, passwords, social security numbers, credit card numbers, and bank account numbers. Phishing continues to be a primary weapon used by cybercriminals. Phishing is often used as the lead action followed by malware installation or other malicious actions that lead to a data breach. Statistically, 85% of organizations have reported being the victim of a phishing attack (Wombat Security, 2016). Spear phishing email, one example of phishing, was the starting point that led to 91% of successful cyberattacks and the resulting data breach (PhishMe, 2016). In addition, phishing was involved in 70% of all data breaches associated with nation-state or state-affiliated actors (Verizon, 2018).

Phishing attempts may occur in various formats, including email scams, malicious attachments, and fraudulent links and websites. Phishing in nature is a form of social engineering attack that exploits human vulnerabilities of curiosity and lack of awareness and judgment. Individual curiosity and lack of awareness often lead online users to become victims of spoofed and deceptive emails, fraudulent web links and fake websites (Alexander, 2016; Gupta, Arachchilage, & Psannis, 2018). Research on predicting individual susceptibility to phishing shows that certain behavioral traits are correlated to the ability to identify phishing interfaces; it also shows that individuals with greater behavioral curiosity tend to commit more security errors in identifying phishing attempts (Chen, YeckehZaare, & Zhang, 2018).

Online phishing has various types of significant impact on organizational and individual victims. The average direct financial cost of a phishing attack to an organization is over \$3.7 million, which is close to the cost of a typical data breach (Ponemon Institute, 2017; Wombat Security, 2015). The costs may include direct loss of productivity and revenue, business disruptions, and costs to contain malware and credential compromises. Additionally, there may be substantial hidden and indirect costs such as damage to corporate reputation and loss of customer confidence as a result of the data breach caused by a phishing scam (Anderson et al., 2012). Phishing scams are a leading cause for individuals to fall victims of identity theft. Over 17 million individuals in the United States alone were victims of one or more incidents of identity theft in 2014, and the majority (86%) of them experienced fraudulent use of their existing credit or bank account information (US Department of Justice, 2017).

DOI: 10.4018/978-1-5225-9715-5.ch056

To combat online phishing, a variety of countermeasures have been proposed, including education and training, improvement of administrative and security policies and practices, as well as technical solutions and software products. This chapter proposes a comprehensive solution to prevent and protect against online phishing. The following sections will define and describe various categories and types of online phishing, explain the theoretical principles for phishing and how each type of phishing works, and propose and discuss a comprehensive set of solutions, mechanisms and best practices to defend users and organizations against online phishing.

BACKGROUND

The term “phishing,” with a “ph” from earlier phone phreaking to replace the “f” in “fishing,” was first used in 1996 by hackers who were stealing passwords for America Online (AOL) accounts from unsuspecting AOL users, and the first media publications warned consumers about the “phishing” threat in 1997 (Gupta, Arachchilage, & Psannis, 2018; Ollmann, 2017). The earlier concept of phishing was limited to the use of email scams by online criminals to “phish” for passwords and financial data from a sea of Internet users (Ollmann, 2017). But the definition of the phishing has been evolving with various versions. Based on a systematic review of 113 definitions of phishing, Lastdrager (2014) tried to propose a consensual definition: “Phishing is a scalable act of deception whereby impersonation is used to obtain information from a target” (p.8). This definition identified and emphasized the important core concepts of deception, impersonation, information, as well as scalability for mass distribution.

The Anti-Phishing Working Group (APWG), a non-profit international research foundation that specializes in the study of phishing and cybercrime, provides the following definition of phishing that offers a more specific and enlightening focus and directions on the nature and techniques of phishing: “Phishing is a criminal mechanism employing both social engineering and technical subterfuge to steal consumers’ personal identity data and financial account credentials” (p.2). The social engineering component of phishing highlights the nature of victimization by exploiting human weaknesses in phishing. The specific technical subterfuge, or mechanisms and methods of deception, may include using spoofed emails, planted crimeware or malware, online interception systems, or phisher-controlled keyboard interception to trick consumers and steal their sensitive information (APWG, 2018).

Social engineering in the context of online crime is defined as “an umbrella term for a broad spectrum of computer exploitations that employ a variety of attack vectors and strategies to psychologically manipulate a user” (Heartfield & Loukas, 2015, p.1). Social engineering primarily targets human users and exploits human psychological weaknesses. The computer exploitations and attack vectors and strategies include examples of technical subterfuge in online phishing to trick and deceive human users. In *The Art of Deception*, Kevin Mitnick, a former master phisher, concluded that the human factor is the weakest link in security and that successful social engineers usually have strong people skills to win and exploit trust from potential victims while most people believe in and behave with trust and love for each other with a low level of suspicion (Mitnick & Simon, 2002). Accordingly, phishing emails and messages often exploit this trust by pretending to be originated from trusted sources, such as friends, government agencies like the Internal Revenue Service, or service providers like banks or credit card companies.

As a critical component of the modern computing systems, humans create most persistent security vulnerabilities as they control system designs and configurations as well as input and output and make decisions on whether or not to click malicious links in phishing emails (Wash & Cooper, 2018). Research on human psychology indicates that online phishing has been gaining popularity due to the flaw in hu-

Table 1. Industries targeted by phishing

Industries	Percentage

man susceptibility (Kleitman, Law, & Kay, 2018). Recognizing the weak human link, cyber criminals have moved toward increased use of social engineering attacks. The Human Factor report finds that cyber criminals have relied less on the use of indiscriminate automated attack while increasing the use of social engineering with more success and impact through highly personalized spear-phishing campaigns targeting specific individuals (Proofpoint, 2017). As evidence of the effectiveness and impact of the human-driven phishing exploits, the report finds that 99% of email-based financial fraud attacks depended on human user clicks on the spear phishing URLs instead of automated exploits for malware installation and that almost 90% of the clicks on the malicious phishing links took place within 24 hours of email delivery (Proofpoint, 2017).

Online phishing via social engineering is a leading cause for identity theft for individual consumers, and about 7% of individuals age 16 and older in the United States were victims of identity theft (U.S. Department of Justice, 2017). In addition, online criminals have been increasingly targeting enterprise organizations by impersonating services such as email service providers and Software as a Service (SaaS) platforms to access and steal corporate data. The latest 2018 Phishing Trends and Intelligence Report shows that phishing continues to be the top threat for cyberattacks and that social engineering to exploit human vulnerabilities continues to be the leading and most successful method of phishing attacks (PhishLabs, 2018). Table 1 below shows the industries targeted by phishing based on the findings from the report by PhishLabs (2018). The report also finds that the total number of phishing attacks went up by two percent in 2017 and that these five industries were the target of over 84% of all phishing attacks in 2017: email/online services, financial institutions, payment services, cloud storage/file hosting services, and e-commerce companies (PhishLabs, 2018).

The trends and techniques in online phishing are dynamic and may provide insight on the how and why the victims and organizations are targeted. Table 2 below shows the major changes and trends in phishing volume based on the findings from the report by PhishLabs (2018).

The data in both Table 1 and Table 2 above indicate that online phishers continue to target corporate organizations, such as email/online services and financial institutions probably for maximum profit. Phishing attacks targeting Software-as-a-Service (SaaS) and Social Networking soared with growths of 237% and 190% respectively. The exceptional increases in phishing attacks on SaaS, such as Adobe and DocuSign, is less about gaining access to the SaaS services but more about using the trustworthi-

Payment Services	+14%		

Source: PhishLabs, 2018

ness of the SaaS brands to social engineer victims into giving up their email credentials (PhishLabs, 2018). Social media platforms may allow creation of fake identities and provide opportunities for social engineering attacks and obtaining sensitive personal information (Krombholz, Hobel, Huber, & Weippl, 2015). Social media sites may also be used as a trusted source to lure phishing victims to malicious files and links (Nelson, Lin, Chen, Iglesias, & Li, 2016). The fast growing phishing attacks targeting social media platforms can be attributed to the established trust relationship between users and the platform that could be used by attackers for social engineering to facilitate additional online crime (PhishLabs, 2018).

Using established trust is essential to social engineering for online phishing attacks. Phishing emails and fraudulent websites may employ a variety of technical subterfuge or visual similarity tricks to make them look like trusted or legitimate sources (Gupta, Arachchilage, & Psannis, 2018; Heartfield & Loukas, 2015; Krombholz, Hobel, Huber, & Weippl, 2015; Nelson, Lin, Chen, Iglesias, & Li, 2016). There was a recent surge in the use of the secure HTTPS protocol and free SSL certificates in online phishing sites (PhishLabs, 2018). As consumers are trained to recognize HTTPS as a security indicator for trustworthy websites, online phishers are using the HTTPS protocol to exploit consumers' trust for the protocol and trick them into surrendering sensitive personal information or downloading malware. Ironically, the encryption and security mechanism commonly used for secure online transactions is used by online phishers against consumers. Statistically, there has been a fast increase in the number of phishing sites using the HTTPS feature. The latest trend report by the Anti-Phishing Working Group (APWG) shows that 35 percent of phishing attacks were hosted on Websites using HTTPS and SSL certificates by the second quarter of 2018 compared with only less than five percent of phishing sites using HTTPS and SSL at the end of 2016 (APWG, 2018).

Theoretically, psychological principles of persuasion are the key to understanding how online phishers use social engineering techniques to manipulate phishing victims and exploit their trust. The anatomy of successful social engineering attacks by Bullée et al. (2018) has identified six persuasion principles often used in social engineering attacks. Table 3 below presents the six principles of persuasion, brief illustrations with examples, and their respective percentage of occurrence in social engineering attacks in the order of occurrence from the highest to the lowest.

Each actual social engineering attack may use one or more of the persuasion principles along with other technical or social techniques to deceive the victims of phishing. In reality, there are a wide variety of online phishing types based on their targets and techniques. The following sections will classify and discuss the types of phishing and propose a comprehensive set of solutions.

Table 3. Persuasion principles used in social engineering attacks

Persuasion Principle	Brief Illustration	Occurrence
Authority	The phisher claims that he is from the security department and needs the target's username and password for security updates.	63.3%
Liking	The phisher claims similar background or personal interest to establish rapport and trust with the target.	13.3%
Reciprocity	The phisher claims that he needs the target's login credentials to help solve a real or made-up technical problem for the target.	11.1%
Commitment	The phisher approaches the target multiple times and obtains sensitive information from the target incrementally.	10.6%
Conformity	The phisher claims that the target's peers have provided what he needs in a survey and that the target should do the same.	1.1%
Scarcity	The phisher claims a limited-time offer for online registration to lure and trick the target to register online at the phishing website.	0.6%

Figure 1. Adapted taxonomy of phishing attacks

Source: Gupta, Arachchilage, & Psannis, 2018

TYPES OF ONLINE PHISHING

In terms of mechanisms and techniques used, online phishing can be classified into two general categories or types, Social Engineering and Technical Subterfuge, and multiple sub-types under each category. Such a classification of phishing is illustrated in Figure 1 below adapted from the taxonomy by Gupta, Arachchilage, and Psannis (2018). The types and sub-types in the taxonomy only reflect a relative emphasis and weight between social engineering methods and mechanisms of technical subterfuge as actual phishing attacks may employ a mixture of various methods and techniques.

SOCIAL ENGINEERING

Email Spoofing

The predominate types of phishing using social engineering schemes are email spoofing and web spoofing, or fake websites. Email spoofing may occur in spear phishing or whaling. Spear phishing is the most common and most effective type of phishing, which was the starting point for 91% of successful cyberattacks and the resulting data breach (PhishMe, 2016). Spear phishing uses personalized emails containing malicious attachments or fraudulent web links to target specific members or groups of an organization. Spear phishing attackers often conduct social engineering research about the target to make the phishing emails appear legitimate and from a trusted source (Nelson et al., 2016). Examples of spear phishing include a fake email message that appears to come from your human resources department asking you to click a link to log in to view, download, and print important documents like paystubs and W-2 tax document, or a message seemingly from a technical service company asking you to sign a service contract attached (UC Berkeley, 2018). Such messages are appealing and deceptive to individuals as they use specific and personalized issues of concern and look like coming from the community close to your work or life. Victims who click and open the fraudulent and malicious links or attachments in such phishing emails may have their login credentials or sensitive financial information stolen or have malware, such as ransomware, downloaded and installed on their systems. Whaling is a special type of spear phishing that targets high-rank individuals such as executives of an organization, who may have privileged possession of or access to sensitive data.

Web Spoofing

Web spoofing is using fake websites to phish and trick users into giving up their personal information. A phisher could forge a website that appears identical to an authentic website to mislead the user to enter personal information to be collected by the attacker (Banu & Banu, 2013). A major website spoofing trick is to manipulate the link tag and content to make the web link display an authentic URL whereas it is directed to a fake and malicious URL in the background (Varshney, Misra, & Atrey, 2016). Web spoofing is often combined with email spoofing with the link to the fake website embedded in the phishing email (Gupta, Arachchilage, & Psannis, 2018). For example, a phishing email may include a logo that looks very close or identical to the company logo on PayPal's website and a link to update one's PayPal account information that goes to a nefarious website (UC Berkeley, 2018).

Technical Subterfuge

Cross Site Scripting

Cross site scripting (XSS) is a common web security vulnerability that allows an attacker to inject HTML tags and malicious JavaScript code into the dynamic web page displayed in the victim's web browser where the cookies containing login credentials and session information can be stolen by the attacker (Gupta & Sharma, 2012). There are two main types of server-side XSS attacks: (1) Persistent XSS attacks in which the code injection is permanently stored in the server and affects the subsequent users visiting the web page; and (2) Non-persistent or reflected XSS is the most common type of XSS attack where the code injection is not permanently stored on the server but immediately displayed and executed

by the victim's web browser if the victim clicks on the malicious URL (Manaa & Hussein, 2016). The XSS attacks are technically crafted, but social engineering techniques may also be used by phishers to lure victims to click the malicious web links. The injection of malicious code into web applications is due to the lack of filtering and authentication of web input (Gupta, Arachchilage, & Psannis, 2018).

Malware Phishing

Malware phishing installs malicious software onto the victim's computer, collects sensitive information from the victim and sends it back to the phisher (Gupta, Arachchilage, & Psannis, 2018). Malware used in online phishing includes viruses, worms, Trojan horses, spyware, rootkits, and key loggers. The malware that targets victims often comes in mobile code from webpage download that includes potentially malicious executable code along with text, images, audio, and video. The malware installation is often stealthy without the victim's awareness or consent. Social engineering phishing techniques, such as lucrative offers of free downloads, free trips, and prizes, may also be used to lure the victims to the malware websites.

DNS Pharming

DNS (Domain Name Systems) pharming aims to direct the victim to visit a malicious website by providing a fraudulent mapping of the IP address and the domain name requested by the victim. In a DNS pharming attack, the phisher may set up a fake DNS server for victims to connect to. Alternatively, DNS cache poisoning may be used by phishers to respond and feed local DNS cache resolver with incorrect records and fraudulent IP address pointing to a malicious URL (Banu & Banu, 2013). DNS pharming does not depend on social engineering techniques as it poisons the domain-IP mapping without the victim's awareness or active participation.

Session Hijacking

Session hijacking uses IP address spoofing and Man-in-the-Middle tricks to impersonate a legitimate host, such as a client or server in a network connection and allows the attacker to monitor, eavesdrop, and hijack the network communication and change, delete, modify, forge, and even redirect data to the attacker's intended destination (Whitman & Mattord, 2019). The attacker may also hijack the session key, often in the wireless LAN connections, to steal user credentials for illicit access to data (Gupta, Arachchilage, & Psannis, 2018). Theft of user credentials and sensitive data via session hijacking is a type of digital and technical impersonation without the victim's knowledge.

SOLUTIONS AND RECOMMENDATIONS

Online phishing threats involve both social engineering tricks and technical deceptions that exploit human vulnerabilities and lack of awareness and protection. Therefore, this article proposes a comprehensive set of solutions and recommendations to prevent, detect, mitigate, and defend against online phishing attacks. The proposed solutions consist of anti-phishing awareness education and training and technical controls.

Awareness Education and Training

It is a general consensus in the anti-phishing research community that awareness training and education is the most important solution to improve human judgement and behavior to mitigate and prevent the risks of online phishing attacks. Education is a critical component in the defense-in-depth security model, and user awareness training can lower user susceptibility to deceptive phishing attacks that target human vulnerabilities (Hearfield & Loukas, 2015). Anti-phishing training and education programs and events should be offered on a regular basis by schools, businesses, and government and public services to inform and alert students, consumers, employees, and the public about the risks of social engineering tricks and online phishing attacks and corresponding methods and tools of detection and prevention. The topics and delivery methods may be customized according to organizational and business needs to maximize the effectiveness. Online vendors can help with user awareness training by providing useful anti-phishing cues and messages to educate and remind users about web phishing risks and on how to verify target URLs and security indicators such as the https protocol, pad lock icon, digital certificate, as well as security and encryption standards used for mobile sites, including WPA2 (WiFi Protected Access II) and AES (Advanced Encryption Standard).

Established information security policies, processes, procedures and guidelines should be regularly updated and integrated with user awareness training and organizational communication to strengthen the human factor to defend against social engineering attacks such as phishing (Heartfield & Loukas, 2015; Mitnick & Simon, 2002). Organizational anti-phishing awareness training should include clear communications on phishing related security updates, policies, and procedures. Security policy communication and updates should include regular reminders of user password expiration and updates, adoption of multi-factor authentication for stronger security and user account protection, and DLP (data loss prevention) education to avoid sensitive information in unencrypted emails. In addition, organizations should make users aware of standard internal and external reporting procedures and resources in case of being a victim of online phishing. For example, consumers can report phishing emails to the Anti-Phishing Working Group (APWG) by email at reportphishing@apwg.org and victims of online phishing and identity theft in the U.S. may file a report with the Federal Trade Commission online at <https://www.ftc.gov/complaint>.

A valuable public resource for anti-phishing education and awareness training is the free and up-to-date phishing alerts and advisories published by the United States Computer Emergency Readiness Team (US-CERT). US-CERT also provides important tips on avoiding social engineering and phishing attacks, which include the following best practices for online users to avoid falling a victim of phishing (US-CERT, 2018):

- Be suspicious of unsolicited phone calls, visits, or emails from unknown individuals asking about employees or other internal information.
- Do not provide personal or organizational information to persons of unknown identity.
- Do not respond to email solicitations or click links in emails asking for personal or financial information.
- Do not submit sensitive information online before verifying the website's URL and security.
- Install and maintain anti-virus software, firewalls, and email filters to reduce phishing email traffic and use anti-phishing features offered by your email client and web browser.

A special type of phishing awareness education and training is needed to prevent and mitigate phishing risks for elderly users who are especially vulnerable to phishing attacks (Lee, 2018). According to the FBI 2017 Internet crime report, the total financial losses from online crimes reached \$1.42 billion and those over 60 years old ranked the highest in the total number of victims and the total amount of financial loss (FBI, 2018). More interactive training on the safe use of digital media, online privacy protection, and defense techniques against email and web phishing should be made available to elderly consumers on a regular basis at community centers, public libraries, and senior living facilities.

Technical Controls

Awareness education and training solutions proposed above are of primary significance as they will improve user behavior and judgment in defending against social engineering and online phishing from the client side. Technical solutions, such as implementations of technical controls on the server side, are also necessary to help to prevent, detect, and mitigate phishing risks in the online environment. The following are important recommendations for server side technical solutions to online phishing.

Server side filtering and authentication technology can be used to detect and prevent email phishing. Email filtering includes: (1) Anti-spam filtering used for verifying email origins and other sender details to filter out substantial amount of malicious email traffic; and (2) DNS-based blacklisting to profile, detect, and block traffic from blacklisted sources (Gupta, Arachchilage, & Psannis, 2018). More importantly, mail server authentication technology should be used by the receiving mail server to validate the source IP address of sending server before potential phishing email traffic reaches the target users. In addition, organizations with frequent needs for data loss prevention in emails should consider digitally signing emails. Receiving e-mail servers can be configured to check and validate digitally signed inbound emails and alert recipients of unsigned or invalid emails, and out-bound emails can also be signed with an official corporate digital certificate to assure the recipients of the authenticity and legitimacy of the email (Ollmann, 2017).

Furthermore, DNS-based authentication also helps to block illegitimate domains and mitigate the negative effect of DNS poisoning or pharming. Implementation of Domain Name System Security Extensions (DNSSEC) and its regular updates are also recommended to defend against DNS pharming as DNSSEC provides origin authentication and integrity check of DNS records. With DNSSEC, the resolvers can verify if the data for the DNS query exists or not, if the existing data is from a reliable source and if it has been modified.

Active web monitoring is a useful solution to combating the most challenging type of web spoofing that targets victims with visual similarities. Visual similarity based phishing detection is an example of active web monitoring that checks for similar web pages and user data and generates a warning upon detection of similar web pages asking for the same sensitive information (Gupta, Arachchilage, & Psannis, 2018). Technically, managed service providers may use agent-based bots to monitor URLs and web content remotely and detect unauthorized use of a company's unique logo, trademark and web content against the legitimate company profile and authorized users of the company web resources (Ollmann, 2017).

Web phishing via cross site scripting (XSS) can be technically prevented by web input validation to stop malicious code injection. Client side web browser solutions may degrade the client system performance and web surfing experience (Gupta & Sharma, 2012). XSS attacks are often successful and undetectable to client-side protection strategies because of inherent trust relationships between the user and the website owner (Ollmann, 2017). Therefore, securing web applications with robust content check and input validation on the server side is the best solution to protect consumers from XSS phishing attacks.

The anti-phishing guide from the IBM Internet Security Systems offers the following best practices and guidelines for implementing successful content validation (Ollmann, 2017):

- Never trust data submitted by a user or other application components.
- Always sanitize user submitted data before processing or storing it or giving it to an application user.
- All data must be sanitized by decoding common encoding schemes back to their root character to avoid any unsafe characters used for attempted code injection.
- Replace all harmful HTML web language characters with safe versions to prevent attempted executable code injections using the harmful HTML characters.

To prevent online phishing using Man-in-the-Middle (MIMT) attacks and session hijacking, application providers and developers should avoid accepting session information within a URL, implement timeout and integrity checks for the SessionID for each client request, and revoke and replace expired and invalid SessionIDs (Ollmann, 2017). Additionally, organizations should require or recommend the use of VPN (virtual private network) connections, proxy server with data encryption, and secure shell (SSH) for remote connections to prevent MIMT attacks and session hijacking (Chandel, Kumar, & Yadav, 2017).

Malware phishing often succeeds through user download of malicious software from websites or email attachments. Awareness education and training is critical to the prevention of malware phishing. However, some technical and security implementations at the organization level are helpful solutions as well. For example, Microsoft Office Macros are still the top means of malware delivery as the Microsoft Office macro feature is usually enabled by default (Zurkus, 2018). Moving applications, such as Microsoft Office applications, from local installations to the cloud can provide centralized and more secure control and management of application installation, updates and data management. In addition, regular implementations and use of firewalls, malware scans, and intrusion detection and prevention systems will help prevent and minimize malware phishing attacks.

FUTURE RESEARCH DIRECTIONS

Phishing continues to be a common method for exploiting human vulnerabilities in cyber attacks today, and it remains an important challenge to train users to recognize and avoid clicking malicious links in phishing emails (Wash & Cooper, 2018). The latest state of phishing report confirms that there has been a steady increase in the volume of phishing attacks and that security awareness education and training has become the most important factor in assessing end user security risks to organizations (Wombat Security, 2018). Future research on phishing awareness education and training needs to focus more on how to innovate curricula and delivery methods for training and on how to assess the effectiveness of training. There should also be more research on how to better understand and protect senior citizens in particular, who are especially vulnerable to online phishing.

With fast growing Internet of Things (IoT) devices and connections, IoT security research needs to address IoT phishing risks and defense mechanisms. As IoT security is still weak, hackers are able to use thingbots, or botnets of infected IoT devices, to relay malicious emails without resorting to malware (Gupta, Arachchilage, & Psannis, 2018). Therefore, how to prevent phishing with IoT devices will be an interesting and important challenge for future research.

CONCLUSION

This article introduces and defines online phishing, which is an online crime of deceiving users into accessing fraudulent emails, web links and websites to steal their sensitive private information. Online phishing is the top starting point for cyberattacks and the leading cause for identity theft that brings financial and other losses to individual and organizational victims. Phishing is primarily a social engineering attack that exploits human vulnerabilities due to lack of user awareness and protection. This article classifies phishing into two groups based on the primary method and technique involved: Social Engineering and Technical Subterfuge. The social engineering group includes web spoofing and email spoofing. Technical deceptions include cross site scripting, malware phishing, DNS pharming, and session hijacking. The primary solution to combating online phishing should be user awareness education and training to improve human behavior and judgment in order to minimize the occurrence of phishing victims. Technical solutions, best practices, and guidelines are also offered in this article to help create a more secure environment to prevent and detect online phishing. This article recognizes that there are significant questions and challenges for future research on phishing, such as on how to design, deliver and assess effective phishing awareness education and training and how to combat and prevent phishing in the emerging IoT environment.

KEY TERMS AND DEFINITIONS

Cross-Site Scripting (XSS): Injecting malicious code to be displayed in the victim's web browser to steal the victim's credentials.

DNS Pharming: Providing a fraudulent DNS mapping to direct a victim to visit a fake and malicious website.

Identity Theft: The crime of stealing sensitive personal information, such as usernames, passwords, date of birth, social security number, and personal and financial information.

Online Phishing: An online criminal attempt via fraudulent emails, web links, and websites to trick online users to surrender sensitive private information.

Session Hijacking: Using a spoofed IP address or Man-in-the Middle techniques to impersonate a legitimate host to eavesdrop or redirect network communication.

Social Engineering: An attack that uses personal and social skills to persuade the target to behave in violation of security principles.

Spear Phishing: Phishing for sensitive information by using personalized emails containing malicious attachments or fraudulent web links to target specific members or groups of an organization.

Technical Subterfuge: The act of deceiving victims and stealing their sensitive information by technical means.

Web Spoofing: Using fake websites to phish and trick users into giving up their personal information.

Whaling: A special type of spear phishing that targets high-rank individuals such as executives of an organization.

Crime Hidden in Email Spam

Wichita State University, USA

INTRODUCTION

Crime on the web has gained significant attention in recent years. In the past, the study of cybercrime was not exactly new but it was by no means a focal concern in the mainstream criminology. Nowadays, however, it seems every crime could have a cyber-related component in it and therefore potentially all crimes can be committed or facilitated by the use of cyberspace. For example, even though you still cannot murder or rape someone on the Internet, you could stalk your victim on the Internet beforehand or you could video-record the crime and sell the footage in the black market. Typically such online black markets exist on the so-called Dark Web or Deep Web. On the Dark Web, you can advertise anything you have to offer or you might find anything you need with a price. Conceivably many things happening on the Dark Web are not legal. Otherwise, they could have simply done the transaction on Amazon.com. In other chapters, the definition of the Dark Web has been provided and how it functions has been discussed. Instead of repeating them, this chapter focuses on how information is being disseminated in the cyber-criminal-world since criminal activities on the Dark Web cannot be Googled. More precisely, the focus is on email spam and the role it plays in facilitating criminal activities that may or may not necessarily take place on the Dark Web. Email spam has long been dismissed as a trivial crime that does not usually warrant much attention from either academics or practitioners. Nonetheless, its low-profile status among crimes may have actually endowed email spam with the best utility in criminal communication.

BACKGROUND

Email spam is defined as unsolicited commercial electronic mail that includes any commercial emails addressed to a recipient with whom the sender has no existing business or personal relationship and not sent with the consent of the recipient, and commercial electronic mail is defined as any electronic mail message the primary purpose of which is commercial advertisement or promotion of products or service (Rogers, 2006). Sending spam emails can be treated as a criminal offense in the United States, according to the CAN-SPAM Act enacted in 2003. The Act imposes penalties on sending unsolicited commercial email if the provisions set by the Act are violated. The Federal Trade Commission (FTC) is in charge of enforcement of these provisions and it also provides regulations of which any violation can be declared criminal (FTC, 2009). The FTC regulations are as follows: 1. Don't use false or misleading header information; 2. Don't use deceptive subject lines; 3. Identify the message as an ad; 4. Tell recipients how to opt out and honor opt-out promptly; 5. Monitor what others are doing on your behalf (FTC, 2009). In 2008, the so-called "Spam King" Robert Soloway was convicted under the CAN-SPAM Act and was sentenced to 47 months in federal prison (Rabinovitch, 2007). The Act also allows states and Internet service providers to file civil lawsuits against spammers (Ford, 2005; Yeargain et al., 2004). Despite this, email spam has never been seen as a serious crime even though email spam is probably one of the most

DOI: 10.4018/978-1-5225-9715-5.ch057

prevalent crimes as almost every person who uses email has received at least some unsolicited junk emails that aim at advertising, phishing or scamming. Most people tend to simply delete them or rely on the spam filter embedded by the service provider to screen them out. However, spam filters are not entirely reliable. As a result, users often have to check the spam folder to see if some important messages have been mistakenly flagged as spam (i.e., false positive). A false positive could cost a delay or omission in an important communication and sometimes this could entail significant consequences (Weinstein, 2003). Therefore, it is an understatement to say email spam is nothing more than a nuisance. In fact, email spam can be costly. Some research has indicated that the time and productivity wasted on account of email spam can amount to 20 billion dollars every year (Yeargain, et al., 2004). The energy used to transmit, process, and filter spam can be equivalent to the electricity used in 2.4 million households annually (McAfee, 2009). In addition, the cost of email spam can be much higher when it is being utilized as a communicative avenue for criminal purposes, such as scam, illicit drug selling, and sex crimes (Yu, 2015a). Unfortunately, the link between email spam and other crimes has long been overlooked. Accordingly, in this chapter the criminal activities associated with email spam are discussed regarding how email spam is being used by criminals to reach potential customers and victims.

FOCUS OF THE ARTICLE

Scam/Fraud

Money is a common motive behind a variety of crimes and email spam is one of these crimes. While many spammers send advertisements to promote commercial products, some spammers resort to scam or fraud. Some scam schemes are elaborate while others could seemingly lack sophistication. Many people are familiar with that Nigerian prince who is looking for someone to help him move money around, and he allegedly is so grateful that he is willing to pay the helper a whopping proportion of his fortune. In addition, many people are lucky enough to have won a lottery they do not remember buying, but no matter how big the winning prize is the lucky winner somehow is always asked to pay a processing fee first. Lately, scammers seem to prefer impersonation. They might pretend to be the IT department in your organization and ask for your passwords, or they could pretend to be your bank and ask for your account information. These schemes are getting old but at least the scammer is willing to make up a story. Some schemes are simply carried out in an email that has only one or two sentences, such as “you have a message; click here.” However, they could work as well thanks to people’s curiosity. Phishing is a very popular way of luring people to visit a website where the actual scam will take place so that the scammer does not need to disclose too much in the email. This method also allows scammers to remain hard to trace by using a false sender address or changing servers, because they do not need to wait for your reply. If they need to wait for the recipient to reply like the Nigerian prince usually would, it means the scammers have to stay active on the same email server for a while, which increases the odds of being caught.

Regardless of the scheme being used, in essence scammers are trying to acquire sensitive personal information so that they can either use it directly or sell it for profit. Figure 1 is an example of scam email. It is typical for scammers to try to establish contact by implying you are the chosen one but they cannot really address you by your name because this identical email was sent to possibly hundreds or even thousands of people at the same time, which is characteristic of email spam. This is especially true in the past when spammers mostly rely on a web crawler to collect email addresses randomly from

From: CENTRAL BANK OF NIGERIA <telx@centralbkng.org>
 Date: 2000/1/2
 Subject: OVERDUE CONTRACT/INHERITANCE PAYMENT
 To:

ATTN: BENEFICIARY.

THIS IS TO OFFICIALLY NOTIFY YOU THAT YOUR OVERDUE CONTRACT FUNDS HAS FINALLY BEEN APPROVED FOR IMMEDIATE PAYMENT BY THE NEW PRESIDENT HIS EXCELLENCY GOODLUCK JOHNSON (GOON) VIA MY ESTEEM OFFICE AS THE CHANCELLER GENERAL FEDERAL REPUBLIC OF NIGERIA (FRN). AS A MATTER OF URGENCY NOW, I HAVE ALREADY DUSTED YOUR FILE SINCE LAST WEEK BEFORE I DEEMED IT FIT TO CONTACT YOU IN REGARDING TO THIS DEVELOPMENT IN FAVOR OF OUR DEAR UNPAID FOREIGN CONTRACTORS WHO EXECUTED CONTRACT GENUINELY WITH OUR DEAR GOVERNMENT BUT STILL REMAIN UNEARD DUE TO THEIR DEALING WITH SOME FAKE OFFICERS WHO ARE IMPERSONATING SOME TOP OFFICERS IN GOVERNMENT BY USING FORGED LETTER HEADED PAPERS AND OTHER FEDERAL GOVERNMENT RELATED DOCUMENTS TO PRACTICE FRAUD THROUGH DIFFERENT MEANS.

IN VIEW OF THIS NOW, A TOTAL SUM OF USD 10,000,000.00 (TEN MILLION UNITED STATES DOLLARS) ONLY, HAS BEEN APPROVED TO BE PAID TO YOU IN THIS FIRST QUOTA VIA INTERNATIONAL WIRE TRANSFER ISSUED IN CARE OF FIRST BANK OF NIGERIA PLC AND YOUR BALANCE WILL COME UP IN THE NEXT QUOTA. BE OFFICIALLY AWARE THAT THIS DEVELOPMENT CAME UP LATE LAST WEEK AFTER OUR CLOSE DOOR MEETING WITH NATIONAL HOUSE OF ASSEMBLY MEMBERS IN CONJUNCTION WITH THE SENATE PRESIDENT (SENATOR DAVID MARK) CONTACT MR. JOHN ABON (DIR. TELEX DEPT) ON HIS OPEN ACCESS EMAIL BELOW:
 EMAIL: firstbanktelxdept@gmail.com
 Tel: +234-7090933118

AND YOU ARE ADVISED TO FURNISH ME WITH YOUR BANKING INFORMATION AND CONTRACT DETAILS WHICH PROOFS THE GENUINITY AND AUTHENTICATION OF YOUR FUNDS AS A GENUINE CONTRACTOR WITH FEDERAL GOVERNMENT OF NIGERIA (FGN). ALSO YOU ARE REQUESTED TO SEND ACROSS YOUR INTERNATIONAL PASSPORT PHOTOGRAPH OR YOUR DRIVERS LICENCE BEFORE WE CAN CARRY ON THIS EXERCISE WITHOUT FURTHER DELAY.

AND SECURITY REPORT REACHING MY DESK STATED THAT YOU ARE STILL DEALING WITH SOME FRAUDSTERS HERE IN NIGERIA WHO ARE IMPERSONATING MY PERSON AS THE CHANCELLER GENERAL OF THE FEDERATION (CGF) WITHOUT PORTFOLIO BE WARNED TO AVOID PUTTING YOURSELF INTO PROBLEMS AND AS A RESULT OF MUCKING YOU THROUGH FRAUDULENT MEANS.

WE WARNED YOU SHOULD DESIST FROM ANY OTHER AGENCIES RELATED TO YOUR FUNDS LOCAL OR INTERNATIONAL BECAUSE ALL ARRANGEMENT THAT HAS BEEN CANCELLED SINCE LAST WEEK AND THE MANDATE GIVEN TO ACCOUNTANT GENERAL OF THE FEDERATION (AGF) WORLD BANK AUDITORS (WBA) HAS BEEN WITHDRAWN SINCE LAST WEEK DUE TO THEIR INABILITY TO CARRY ON THE EXERCISE AND THEIR ATTEMPT PUTTING OUR DEAR FOREIGN CONTRACTORS INTO FINANCIAL DIFFICULTIES. I WILL LIKE YOU TO CALL ME TODAY ON MY HOTLINE +234-7091236462 FOR MORE DETAILS AND TO YOUR PAYMENT UPDATE. ON BEHALF OF THE FEDERAL GOVERNMENT OF NIGERIA (FGN) WE APOLOGISE FOR YOUR GREAT LOSS AND UGLY EXPERIENCE IN THE PAST.

AWAITING YOUR URGENT CALL.

CONGRATULATIONS AT LAST.

BEST REGARDS,

MR. DAVID SMITH
 DIRECTOR, TELEX DEPT CBN

various webpages. Nowadays, however, more and more spammers acquire a list of email addresses from data stolen from systematic sources, such as the members of popular social media sites or customer information from a bank. This allows them to link each email address to a name or even a social security number in some cases. Therefore, a sophisticated scam email might start by addressing your name correctly and lead you to believe this is an authentic personal email, while in actuality the same email was still sent to a long list of recipients with each person's name customized. It is noteworthy that some scam attempts are indeed personal. It follows that the scammer is targeting you per se instead of a list of random people on the Internet, but this tactic is outside the realm of email spam as sending a personal email does not fit the definition of spam.

Using email spam as the communicative avenue provides two major benefits for scammers. First, it allows scammers to reach a wide range of potential victims. Granted, most people do not take these emails seriously, but the odds of someone actually taking the bait will increase when the scam email can reach more people. Greed and curiosity are the two human elements that scammers are counting on no matter how elaborate or simplistic their scheme might seem (Yu, 2011). Second, hiding scam inside spam provides protection for scammers. One standalone email attempting to steal your money could appear alarming or even threatening to many people, but if it shows up in a mix of unsolicited emails, most people would dismiss it as just another junk email. Such dismissal reduces the chance for the potential victims to report crime to the authorities. Otherwise, scam or fraud is actually a much more serious criminal offense than email spam itself and usually warrants more attention from law enforcement.

To date, there is no reliable estimate on how many people actually fall victim to these scam emails every year and the cost of such scam remains unknown, but the number is likely to be in billions including all direct and indirect costs plus the resources spent on preventing such scam (Anderson et al., 2013; Whitty, 2013; LexisNexis, 2017). Certainly scam needs not always rely on email spam to carry out and the motive may not always be financial (Whitty, 2013), but in this chapter the focus is on how email spam may lead to scam and fraud. The link between email spam and scam is important as the content of scam emails may serve as evidence and the header information in each email, despite the likelihood of spoofing, could provide traces leading to the criminal's location (Yu, 2011).

Illegal Transactions

Although scam or fraud is a common theme in email spam, most spam emails are being used as advertisements (Yu, 2011). Generally, spam is a cheap way to promote a business on the Internet. The main benefit of using email spam for advertising lies in its ability to reach a very large population with little time and technical difficulty. As mentioned above, the FTC does not exactly ban sending commercial emails as long as the regulations are met. Spammers do not particularly care about those regulations however (Yu, 2011; Yu, 2014), mainly because of the small perceived likelihood of them being caught and punished in spite of the CAN-SPAM Act. Spammers are more concerned about how to make sure the email arrives in the recipient's inbox rather than the spam folder. Their biggest obstacle is the spam filters, not legal deterrence (Yu, 2011). Although most spam emails will not pass the spam filter and even if they do very few recipients would pay much attention to what is being advertised in the email, unsolicited commercial emails are still rampant on the Internet. Since the cost and risk are both low, many online merchants who cannot or would not afford traditional advertising still view email spam as one viable way to draw at least some attention to their business. These are the merchants who run an otherwise legitimate business and they just need a way to reach potential consumers. In contrast, for the merchants who are running an illegitimate business, email spam for advertising is even more fitting to their criminal activity.

In theory everything can be advertised in email spam, but the most commonly seen products are drugs and pornography (Yu, 2011; Yu, 2014). The drugs being advertised are usually prescription drugs coming from unknown sources. There is little guarantee they are authentic drugs, which makes the potential harm of this type of email spam much greater than simply an annoying email. It can pose a threat to public health. It is a well-known fact that drug abuse is a serious issue around the world, so conceivably there must be a market for this type of business. Aside from prescription drugs, illegal drugs can also be distributed this way. Many of these illegal transactions take place on the Dark Web (Maddox et al., 2016), but there is still a need to advertise the products first before people know where to look. This is when email spam becomes helpful. Normally, the instructions regarding how to complete transaction are not obvious in the spam email. Usually there is a link in the email leading potential clients to more instructions or contact information, but the link is usually time-sensitive to avoid being traceable. Unlike those merchants running legitimate businesses, online drug sellers do not usually make an effort to beat the spam filter (Yu, 2011). They are fine with their emails being flagged as spam, because their clients usually would actively look for these emails to initiate transaction. Besides, similar to scam, hiding drug-selling emails in the spam offers protection due to the low-key status of email spam.

Other than drugs, pornography is also a commodity regularly appearing in email spam. Sex-related crimes will be discussed in detail in the next section. A less common or less obvious crime hidden in email spam is e-fencing. Fencing is a century-old practice closely related to property crime. After crimi-

nals steal property, they usually need an outlet to sell the stolen property in a clandestine manner so that the police cannot trace the property back to the offender. This outlet has to be reliable and resourceful. The person providing such an outlet is called a fence and the practice of selling stolen property is called fencing. With the help of technology, today's fencing can be efficiently done electronically (Carver, 2014; Yu, 2015b). E-fencing reaches a larger pool of potential customers and allows the transaction to transcend geographical limits. In addition, the cyberspace always provides a certain degree of secrecy that is very appealing to criminals. Not unlike merchants who need advertising to promote business, e-fencing needs to promote their products to potential buyers as well. As such, email spam is a good option for e-fencing. Although technically there is no practical reason to stop the fence from just listing the products on Amazon or eBay or craigslist, some stolen property is unsuitable to be sold so publicly. In this case, the use of email spam is not aimed at reaching a large group of audience. Rather, it is using spam as a disguise. The advertisement might appear to be promoting some common items, but the true intention is to inform insiders of the availability of certain commodities. In fact, this tactic could be used by drug sellers as well. When the supply is limited, there is no need to advertise it to too many people but it is still imperative to notify insiders of the availability. In a way, it is a method of masquerading incriminating communication as email spam. How email spam facilitates covert communication will be discussed further in a later section.

In sum, email spam can be a gateway to a criminal world where illegal transactions are taking place. Since this criminal world could position itself on the Dark Web and become relatively hard to find, it still needs to attract more clients from regular Internet users and email spam is one way of advertising it without drawing too much unwanted attention.

Sex Crime

As mentioned, for the most part email spam is being used for advertising. Sex is one of the commodities that could be the center of such advertising. In fact, sex is one of the most prominent themes in email spam (Yu, 2011; Yu, 2014). Pornography is rarely being advertised openly in conventional media but it is easy to find on the Internet nonetheless. Many pornographic websites, such as Pornhub frequently rank high in the most visited websites list (Alexa, 2018). However, not all pornographic videos or photos are free to be shared online. Some are made for profit and being shared or sold without the copyright holder's permission, which constitutes copyright infringement. As such, even if the content of pornography is not illegal, the sharing and selling of it could be illegal. Similar to what was discussed in the previous section, illegal transactions of pornography oftentimes rely on email spam for advertising. Other than pornography, sex-enhancement drugs and toys are also popular commodities frequently advertised in email spam. Although mostly these are simply some people trying to sell their products and the use of email spam entails nothing more than advertising, there are some scammers who would incorporate sex into their scam schemes. It could be a scam in which the buyer pays and does not receive the product, or they might receive counterfeits. When it is sex-related, the victims are less likely to report it to the police because most of them find it embarrassing to disclose what they were trying to buy and this is what the scammers are counting on. How many people would want to tell the police they tried to buy Viagra online and got scammed, for instance? For scammers, sex is so enticing and unspeakable that it is a perfect ruse to be deployed.

However, scammers do not merely rely on shopping scam when it comes to sex. An emerging trend is online romance scam. In this crime, criminals pretend to initiate an intimate relationship through an online avenue, and after gaining trust the objective is usually to defraud the victim of money (Whitty &

Figure 2.

Buchanan, 2012). This form of scam mostly occurs on online dating sites or some classified advertisements being used by many people to seek romance. These dating sites are ideal for a hunting ground because when the victims already possess a mindset to actively look for intimate relationships, it is fairly easy to manipulate them into trusting a scammer wearing a “true love” disguise. However, in addition to targeting romance seekers, some scammers also resort to email spam to widen their net. Figure 2 is an example of spam email of this type. The content of the email links to another website that features many female photos with seductive messages. It could be a scam or a simple advertisement, but its sexual connotation is no question.

Most sex-related spam emails are promoting something that does not necessarily need to hide on the Dark Web. Hiding in spam could suffice in most cases. Nevertheless, some sex-related commodities are much more suitable to be kept on the Dark Web as hiding in email spam is not dark enough, such as child pornography and human trafficking for sex. Porn exchange is fairly common on the Internet, including the Dark Web (Chertoff & Simon, 2015). On the Dark Web, the main appeal is that anonymity is usually easier to achieve. Many Dark Web social networks have emerged for like-minded people to become associated more conveniently without the state regulation, and pedophiles certainly are utilizing them (Bradbury, 2014; Gehl, 2016). While some of these criminal networks are intentionally being kept in small circles, others are definitely trying to expand their clientele and attract more business. In this regard, email spam once again is sometimes seen as a suitable way of advertising. A close examination of this type of spam emails would reveal that some advertising emails do not link to a website accessible from a regular web browser. Instead, these advertisements contain only instructions for accessing the Dark Web (Yu, 2015a). These instructions may be hard to discern for those who are not particularly familiar with the Dark Web, and they might even be encrypted. It is not uncommon to see coded messages in email spam (Yu, 2015a), but most people tend to dismiss them as gibberish as one would expect to see in junk emails. How email spam can be used to convey covert messages is discussed in more detail in the following section.

Covert Communication

Email is essentially a tool for communication. It is convenient because of its extremely low cost and its prompt delivery for the most part. While in modern days most people probably prefer to send text messages through a cell phone, email still holds its place in electronic communication as it allows for longer and more organized messages to be sent. With HTML, the content of an email can be a lot more

enriched and artistic if needed (Yu, 2011). However, in the criminal world, the primary concern is usually about being untraceable whereas being untraceable oftentimes implies inconvenience. In this regard, email spam provides an option for criminals to communicate with a lower risk of being detected and at the same time still enjoy the benefits of email, such as low cost and promptness. It is important to note that criminals certainly may use a variety of methods to facilitate covert communications and it is by no means being suggested that email spam is the primary method or the best method. Nonetheless, it is a viable option particularly because of the lack of attention email spam is receiving.

Mainly, there are five general methods that can be applied to email spam in terms of covert communication. First, the message can be inserted in an advertisement and disguise as spam. Without a close look, most people would not notice the message. Even if they notice, they probably will not know what that message is referring to. Usually the intended recipient is the only person who knows the context enough to make sense of the message. For instance, the message may contain information about time and location without clarifying what this information is for, but the intended recipient should know (Yu, 2015a). Second, encryption may be used. More sophisticated criminals, such as terrorists, would want to further disguise their messages by means of encryption (Yu, 2015a). Anyone can easily create a coded message but the real challenge is whether the recipient can decrypt it. For example, `upnpsspx` is an encrypted word for “tomorrow”. The encryption is fairly simple as it shifts each letter to the next letter in the alphabet. However, if the recipient does not know that, then `upnpsspx` is a meaningless word, and thus communication will not be successful. In this case, again the criminals on both ends of communication should possess some prior knowledge about the context so as to communicate effectively with encrypted messages. When encrypted messages appear in a normal email, investigators would naturally want to decipher them and therefore the risk is higher. In contrast, when encrypted messages appear in spam emails, most people would not think too much about it, because random text has been commonly seen in spam emails since inserting random text is one of the popular ways in the effort to deceive spam filters (Yu, 2011). The purpose is to mislead the spam filter to believe the message is unique since each one has a different text string inserted, which may reduce the chance of being flagged as spam. Encrypted messages may look like such random text and therefore be overlooked.

Third, a message may not be revealed in the email itself as email serves as merely a link to a different place (Yu, 2015a). As mentioned before, many spam emails contain only a link to another website. Criminals could use these links to guide the recipient to where the message is hidden. The message could be hidden on a blog in one of the articles or in the fine prints on some credit card application website, for instance (Yu, 2011). Lately, some voice message services allow people to leave a voice recording and the intended recipient can access the voice message through a link in the email. This way, there will be no phone record but the voice communication can still be accomplished. In addition, it can be hard to trace or prove who is leaving such messages. Disguising this type of email as spam offers deniability because the recipient can deny being the intended recipient, since spam supposedly is sent to multiple random people at once.

Fourth, steganography is a technique that is widely used to hide an electronic file inside another electronic file and therefore the hidden file becomes hard to be detected. For instance, a pedophile may hide child pornography inside an innocent looking vacation photo. Without a further analysis, it is very easy for such incriminating evidence to be overlooked. With steganography is incorporated into email spam, it provides double disguise for covert communication (Yu, 2015a). It is not uncommon for spammers to use images as the content of their email. The image usually looks like regular advertisement. Inside the image, however, something more sinister could be hidden. It could be a text message, a picture, a document, or even a recording. Most people, including criminal investigators would tend to see only what

the image looks like without suspecting other electronic files could be hidden inside. This is inevitable considering the volume of electronic files one may discover in any given device or any online account, such as Instagram. It is simply infeasible to take a close look at every file. By far, there is no forensic software that can offer a quick scan through all electronic photos uncovered in a device and reliably flag possible use of steganography. Hence, steganography can be a very effective tool for communication among criminals to be undetected. On the other hand, if the recipient does not realize there is a hidden file or is unable to extract it, then steganography will actually defeat the purpose of communication.

Fifth, forged header information in a spam email could contain the real message rather than in the content (Yu, 2015a). It is a known fact that many spammers consistently use false information in the header, such as a fake sender's email address (Yu, 2011). It is a blatant violation of the regulations stipulated in the CAN-SPAM Act, but as mentioned, spammers are not usually too concerned about the Act. Using a fake name or email address normally is an attempt to conceal the true sender's information and to make the email look believable. For example, when the purpose is scam, by using forged header information scammers try to let the recipient believe the email comes from a legitimate source, such as your bank or school. Since it is a common tactic employed by spammers, no one would find it suspicious when criminals are actually using the header to convey the true message instead of the content. The content may look like regular spam advertising or it could be empty. It has been found that criminals could use fake header information to provide instructions on how to access the products on the Dark Web (Yu, 2015a).

In sum, while spam email has rarely been taken seriously, its low-profile status offers ideal disguise for criminals who do not want their communication to be detected. Making personal communication look like email spam could avoid attention since everyone using email nowadays would typically receive several spam emails on a daily basis and thus become insensitive to it. Even if the message is being suspected, spam offers deniability because spam usually targets a large group of random recipients. It is important to note that sometimes the email is merely designed to look like a spam email but the message is still only sent to the intended recipients, whereas sometimes criminals use real spam to send a message, in which case many random people could receive the same message but they will not know the significance of it. Either way, when the communication is covert in nature, the intended recipients need to possess some prior knowledge so as to know what to expect and how to use the information they receive. Otherwise, cover communication by means of email spam might deceive not only the authorities but also criminals themselves.

Malware

A recent trend has emerged as more and more malware is being disseminated through email spam. This type of spam is usually referred to as malspam. According to Multi-State Information Sharing & Analysis Center (MS-ISAC), malspam has become the number one method by which malware is being sent to unwitting people around the world (MS-ISAC, 2018). There are many types of malware. One common purpose is to function in the background of a computer system without the user's knowledge, and thereby provide remote access for the criminals (e.g. Trojan). The malware may be logging key strokes so that criminals would know what you type in for passwords, or malware may be stealing data from the infected computer and transmitting such data to the hackers. Some malware, also known as ransomware, could freeze a computer and thus deny the rightful user access until the user pays a ransom, usually in the form of cryptocurrency, such as Bitcoin (Patil & Patil, 2016; Chen et al., 2017). Ransomware may simply lock or encrypt the data but some more malicious variants could wipe the hard drive clean even when the ransom has been paid. Malware also is commonly used to create a botnet that can be used for criminal

purposes, such as launching denial of service attacks or secretly using other people's computers to mine cryptocurrency. Since almost no one would voluntarily download or install malware onto their computers, a clandestine way of spreading it becomes imperative for criminals. As such, email spam provides a way. Similar to using email spam to send advertisements or scam emails, malware can be hidden in a spam email with click bait. Once the recipient clicks on the link or downloads the attachment, malware could be successfully landed in the computer system. Recently, one frequently used ruse in malspam is fake mail delivery notification. In this type of spam, the email usually appears to come from UPS or FedEx notifying you that you have a package waiting for you and you should click on an embedded link to see more information. Typically the link would trigger downloading of malware that the user might not notice (Tellenbach et al., 2016; Matwyshyn, 2006). The distribution of malware used to heavily rely on pop-up windows that are associated with many underground websites that promotes pornography or online gambling. Usually users need to click on quite a few of those advertising windows before they can finally see what they came there to see. While users think they are simply closing those pop-ups, through clicking they probably have unknowingly introduced some malware onto their computers. This method has been largely ineffective now as more people are using ad-blockers to avoid these pop-up windows from showing. As a result, malspam became a new favorite method.

The personal data collected through malware could be sold in the black market, especially when such data are stolen from government agencies. Government agencies and big companies are among the most popular targets when it comes to malware (MS-ISAC, 2018). However, criminals certainly do not mind collecting some sensitive information from individual users as well. Many criminals attempt to plant malware even though they may not possess any advanced knowledge about computer networking because there are tools readily usable to disseminate malware. They may be found on the Dark Web and might even be attainable by a simple Google search. Once again, email spam provides such operations with some protection by means of its low-profile crime status and low cost.

SOLUTIONS AND RECOMMENDATIONS

Given the close links between email spam and other crimes, there is a need to develop better techniques or programs for further analyzing spam emails and tracing their origin. The volume of spam emails that are being sent on a daily basis is amenable to the generation of big data, when they are systematically collected. Analysis on such data can potentially uncover more about email spam's involvement in the criminal activities taking place on the Dark Web or otherwise. It is unrealistic to assume the Dark Web is somehow completely separated from the rest of the Internet. Criminals do not always stay in the dark. Email spam has been used as the gateway to the Dark Web and it has served as one advertising method for Dark Web marketing, such as drugs, guns, child pornography, and sex slaves (Yu, 2015a; Yu, 2015b). Email spam can also be used by terrorists to hide communication (Yu, 2015a). Since spam emails may contain multiple languages and various coding schemes, a more consolidated effort as opposed to individual projects is warranted to perform comprehensive analysis on spam emails. Before this can happen, both practitioners and academics need to recognize the full potential of email spam in terms of its criminal involvement, which is much more than the scope of the CAN-SPAM Act. For email users, to reduce the risk of being victimized by the schemes hidden in email spam, caution is much needed. Users should manually report spam and be careful before clicking on a link or downloading a file from email. Users may also report scam, malware, or other email crimes to the FBI's Internet Crime Complaint Center (IC3). However, it is unlikely for the FBI to launch an investigation for every complaint they receive.

FUTURE RESEARCH DIRECTIONS

Currently, most research about email spam is only devoted to training spam filters to accurately identify or block spam. More attention needs to be paid to the content and the context of email spam. First, big data need to be generated and the data need to include a variety of sources so as to capture the full scope of spam. For example, most Americans probably never received spam emails written in Chinese or German, because the user's Internet habit will determine what kinds of spam they are most likely to receive. Omission is likely to happen if spam is collected from homogenous sources only. Second, machine learning (e.g. text analytics) can be employed to train computers how to classify spam emails based on the content and how to identify possible covert communication, such as the existence of coded messages or steganography. Third, after covert communication is detected, further analysis needs to be developed to decipher the message. Research in this regard is inevitably interdisciplinary in nature. It requires knowledge from criminology to understand criminal operations and criminal mindset. It needs expertise in computer networking to understand the Web and email systems. It also requires linguistic knowledge to analyze the content, and when foreign languages are involved some cultural understanding is crucial. Cryptography can be relevant as well in dealing with encryption. In sum, research on email spam is not new but research on in-depth spam analysis remains uncharted territory. It has merit to look further into the connection between email spam and other crimes and it calls for interdisciplinary efforts.

CONCLUSION

In this chapter the objective is to illustrate the potential connection between email spam and other crimes, such as illegal pornography, illegal drug selling, scam, malware, human trafficking, and so on. Regardless of what type of crime is being associated with email spam, the appeal offered by email spam is mainly related to the fact that very few people are paying attention to the context of spam emails as most attention is on how to block spam. Although most spam emails are indeed being blocked (Yu, 2014), spammers' endeavor continues nonetheless, which suggests spam is still serving a purpose to some extent. Researchers should not be content by keeping spam in the spam folder. Ignoring the information contained in these so-called junk emails is counterproductive in terms of intelligence-led law enforcement because intelligence can be rich in these spam emails if carefully analyzed. Such intelligence may lead to more understanding on the operations of criminal organizations and the social dynamics of the Dark Web.

KEY TERMS AND DEFINITIONS

4

Covert Communication: Communication through methods that are designed to make such communication undetectable or unsuspecting.

Dark Web: Refers to websites that exist in an encrypted network that cannot be found by regular search engines and cannot be visited through regular browsers.

E-Fencing: Selling stolen property on electronic platforms to make it look like normal electronic commerce.

Email Spam: Unsolicited emails that are usually sent in bulk to nonspecific recipients.

Malspam: Spam emails that carry and deliver malware.

Malware: Malicious software that is designed to compromise a computer, server, or a computer network so as to gain unauthorized access or to cause damage.

Scam: A dishonest scheme used to deceive and manipulate a person into voluntarily providing valuable assets or information.

Steganography: A technique that aims to hide information or files inside an electronic file so that no one suspects such files or information is being delivered.

Classification of Spamming Attacks to Blogging Websites and Their Security Techniques

INTRODUCTION

With the explosive expansion of information on the World Wide Web, search engines are becoming more and more significant in day to day lives of humans. In China only, there are more than one twenty million Internet users, among which just about eighty percent use search engines regularly and eighty eight percent using search engines as a key means to acquire newly appeared information (Liu et al., 2008).

Even though a search engine generally gives huge number of results for certain query, the majority of the search engine users simply view the first few web pages in result lists. Consequently, the ranking position has become a most important concern of internet service providers.

Spamming is the method of intentionally manipulating HTML pages to achieve high ranking of search engines. Spamming is exploited to deceive search engines indexing program and to gain ranking position.

The spammers exploit vulnerabilities in web application especially Blogging sites. Security issues in Blogging Websites are still exploratory and in spite of an increase in Blogging Websites research and development, lots of security challenges remain unanswered. Spamming are the most malicious threats to the web application, especially Blogging Websites (Rahman et al., 2008).

The main objective of this chapter is to examine to what level spammers could be threat to Blogging Websites. In first section the terms related to spamming are defined, and a sufficient overview of spamming will be presented in order to give the reader with an understanding of the background for the remaining Sections.

The subsequent section will present the indications and signs of spamming attacks. This section will provide the information of different categories of spam such as Content Spamming and Form Spam. A section devoted to Security Techniques including detective and preventive techniques will be presented.

The first section introduces the overview of web spamming including Content Spamming and Link Spamming, Click Spam and Form Spam. Further, this section elaborates the attacks form spamming on blogging Sites.

DOI: 10.4018/978-1-5225-9715-5.ch058

The next section presents the vulnerabilities in blogging sites their types and vulnerability scanners.

The last section presents the taxonomy of detection and prevention methods such as various forms of CAPTCHA, and Honeypot. It also explores the Data mining techniques including Support Vector Machine. At last conclusion of the chapter is presented.

TYPES OF WEB SPAMMING

Content Spamming

Content Spamming is the first and most widespread type of web spam because it exploits search engines based information retrieval models. These models are build from page contents which further ranks the pages on the bases of the page rank algorithms. As the result the spammers analyse the weakness of these models being implemented and exploit them. The different types of content spamming are Title spamming, Body spamming, Meta tag spamming, Anchor Text spamming, URL spamming (Henzinger, 2007).

As the title field is very important in the information retrieval, spammers try to overfill it in order to increase the page rank and this type of spamming where one overfills the title is called title spamming. In body spamming the body of the page is modified and injected with certain content or queries that are frequently searched. The meta-tags play a special role in document description as when we use search algorithm n search engines the results are fetched on the bases of the meta-tags on the webpage. So placing the spam in this content will be the most efficient way to spam the document (called meta-tag spamming). Anchors tag are the tags used to include links on the website so in anchor spamming the spammers create the links with the desired anchor text to get the right term for the target page. In URL spamming the content to be searched is itself injected to the URL.

Link Spamming

There are two main categories of link spamming namely

1. Outgoing Link spamming, in this the spammers have direct access to the page and can therefore add any content to the web page. They can easily copy the entire web catalogue.
2. Incoming link spamming, where the spammers try to raise the Page Rank and boost the number of incoming links to the page (Gyongyi et al., 2008).

Cloaking and Redirection

Cloaking is a way to provide different versions of a page to the user/crawlers based on the information contained in the request made or query being searched. The other way is to redirect users to the malicious pages by executing JavaScript. The JavaScript redirection spam is the most widespread and is the one of the most difficult detection spam by the crawlers.

Click Spam

In this type of spamming, attacker executes clicks for end users who have not made them.

Form Spam

Form Spam is one of the methods of submitting web forms with unwanted information. Unwanted information may be advertisements, link to offer pages, phishing URLs and abusive tests. Once the form is filled, it is usually sent to a group mail within the company and then the links are clicked by many, by which the spammer is able to generate the traffic, ad revenue or redirect them to phishing sites to collect the personal information.

The reasons behind these form spam are:

1. Probing for vulnerabilities: The web spammers hope to hijack the websites mail server through the web form and use it to relay their spam. This is all done to exploit the poorly written web scripts (called spam injection).
2. The spammer may want to get the links to some of their spam sites published on the web site being spammed.

But now a days the commercial logic behind web spam are that the modern search engines such as Google, Yahoo, Bing etc. rely heavily on inbound links to rank a web page in their index (that is, the websites with many keywords or the related content or with links on it are ranked the top websites and ranked the top positions on these search engines, and are visited most frequently hence earning the maximum revenue). Also, many websites allow the visitors to publish content on their web pages through completion of web form, example: Comment posted on blogs, “Guest Book” pages on the websites. So in order to earn more revenue from the websites or generating more traffic on the websites servers the spammers create “Bots” (also known as automated web crawlers) to seek out and find pages with forms. After finding such types of pages the bots fills out the form and submits the form, typically with the content that contains lots of links to spammy websites and other irrelevant content. Also, there are many human spammers that manually target websites and abuse their web forms. These spammers are difficult to block as they are able to cross CAPTCHAs and other security measures, but somehow they may not be able to spam a form when it comes to spam count because the frequency with which the bot will fill the forms is much less than the human frequency (Gao et al., 2012).

There are various impacts of form spam for instance, consider an example of Community Forums, which engage thousands of users daily. In such a case the automated form spam comments on the forums as the result the content is seen by number of users, should rather say a number of genuine users because there may be many more human spam users as well. These comments come in between their conversations and the users click on these links as the result this hijacks the entire thread with unsolicited messages. This may affect the website’s reputation as the user experience will spoil resulting in less users on the website and hence less return on investment. So form spam is a huge challenge for classified websites, forums and other job or property portals where lots of users visit on daily bases. So, the target websites are mainly the websites which have lead collection form or contact forms that spammers take advantage of. Sometimes, competitors target websites to create fake leads so that sales teams waste time and energy in pursuing these leads which impacts listing agents (in terms of return on investment) and lose confidence on the website as a result of the spam leads and may choose to opt out.

So, from above impacts we can conclude that the form spam do have a significant impact on the websites and the web users so we need to prevent such spam. No doubt with the advancement in the technologies the spamming has increased and the old methods to recover from this spam are failing. One of the reasons is during early days the websites were made from scratch and were then hosted on

the domains but now a day's everything is done online and on-click. Now a days the user just pay for the things and everything is ready in few minutes. No doubt the work efficiency has increased but spammers have found new ways to spam the content but the research is still in progress to find the methods and techniques to prevent and defence against spamming attack.

VULNERABILITIES IN BLOGGING SITES

Vulnerability Definition

Vulnerability is a cyber security related term which can be defined as a defect, imperfection, weakness, or inadequacy of a system that can leave the system open to attacks. Such imperfection or defects leaves the information security exposed to threats. Due to advancement in technology and digitization it has caused a need to prevent the data from manipulation and further attacks. Vulnerabilities make it possible for the attacker to target system to run their code on the system to exploit information (Ten et al., 2008).

TYPES OF VULNERABILITIES IN BLOGGING SITES

User Enumeration

User Enumeration is a common type of web application vulnerability. This type of vulnerability occurs where there is login page and forgot password functionality. This is done by a hostile user by use of brute force to guess or confirm the valid user.

In a login form if user enters wrong username then server returns a message depicting that the Invalid Username and in the same way if the password is incorrect server return a message depicting Password Incorrect and if both are incorrect then another message pop-up. The malicious actor is looking for such activities and responses by the server and the validity of login credentials so that the malicious actor can use brute force to crack the system (Shah & Mehtre, 2015).

Security Configuration

Security configuration includes all the aspects which uses security configuration. These configurations if misused negatively affect the software applications. Security configuration alludes to the security aspects that are taken care when the installation and building of computers and network devices are done so to reduce the vulnerabilities (Scarfone & Mell, 2010).

Remote Code Evaluation

Remote code evaluation is usually seen in web applications so to get benefit from others work and re-search. In this a remote code is injected in the file or string and its get evaluated by the programming parser. This behavior is not planned by the developer of that web application.

Invalidated Redirects and Forwards

Invalidated redirects and forwards happens when some web application agrees for unauthorized or untrusted inputs that may lead to redirect the web application to the URL that is contained in the unauthorized or not trusted input. By this URL redirection the attacker may cause problems by scamming and then stealing user's credentials. As the modified links is as similar to the original site therefore, it is easy for the attacker to make changes and blockhead the user (Rafique et al., 2015).

Inadequate Application Layer Protection

The application data present may be a weak link in your application which can be exploited and may cause issues in the security of system. If the attacker found the flaw or weakness of the application then he is capable of introducing changes in web application and may commit the crime. Some basic application vulnerability exploits are SQL injection, cross site scripting, cross site request forgery and others.

Vulnerability Scanner

Vulnerability Scanner is a kind of code or program that performs diagnostic phase of vulnerability assessment. It is used for inspection of potential threats at the points in the system to know security loop holes. It establish, explain and arrange the security holes in a system network. There are different types of vulnerability scanners one of the scanner is Nessus. This scanner uses common vulnerabilities and some exposure architecture so that easy cross-linking can be done between security tools. Nessus uses Nessus attack scripting language to establish threats and potential attacks. Vulnerability scans are therefore useful as they establish the weakness of system at the security holes and works according to that (Kals et al., 2006).

There are various types of vulnerability scanners:

WPScan

WPScan is a complimentary vulnerability scanner for non-commercial sites used by blog maintainers and security professionals. WPScan is used on platforms like Wordpress. It is a blackbox vulnerability scanner used in Wordpress. This is used by both professionals and developers. WPScan is a platform that keeps the site safe, but some problems can be solved by simply updating it (in case of plug-in and themes that are vulnerable). The WPScan feature includes directory indexing on discovered plug-in, sensitive information disclosure via exposed log files, vulnerability identification to compare the sites with known vulnerable sites, plug-in and themes enumeration to detect which plug-in are installed and activated, username discovery using username enumeration and many more (Sinha, 2018).

Sucuri

Sucuri was developed by (Daniel et al., 2010) . Sucuri is a well known authority in matters related to security of websites (especially wordpress). This technology is free for all Wordpress users. It works hand in hand with the other existing security software applications. It provides a set of security features to its users. Sucuri scanner detects blacklist warnings, security issues and malwares present in the source code. It helps the system administrator to ensure the security of the website. Its main features are receive

emails notification for secure issues, setup scans as a scheduled task, setup scans as a schedule task, detect website malware infections, view website security details and information and monitor blacklist status.

Pentest-Tools

Pentest is another tool that helps the developer to identify weakness in the web application. This is a platform to find or recognize unknown vulnerabilities in the system that may cause security breach. The pentest tool attack the system from inside in the same way the attacker can perform that from outside the system. There are different types of pentest tools one of them is Netsparker. Netsparker automatically recognize XSS, SQL injection and other vulnerabilities in the web applications. Its features are minimal configuration requires, full scalable solution and many more. Other than this there are many other pentest tools that are used for security of web application such as Zap, sqlmap, Acunetix, probe.ly, owasp, wireshark, w3af, Kali, samauri framework, aircrack, sqlninja, BeEF, dradis, rapid7, hping, superscan, scappy, Ettercap, etc.

THREATS IN BLOGGING SITES

Threat Definition

As per the Oxford Dictionary definition of cyber threat is as “the possibility of malicious attempt to damage or disrupt a computer or system”. This definition is not complete as it does not include the attempt to steal the data or access files or infiltrate data. So this definition defines the threat as a possibility but in terms of cyber security community, the threat is defined more closely to an actor or an adversary who is trying to gain access to a system and have enough potential to do any damage to it.

So in general terms completing the definition of threats in terms of computer networks and network security, threats are the potentials that may cause harm rather serious harm to the computer systems. So in formal terms threats are the potentials for the vulnerabilities to turn to the serious attacks, which are sufficient enough to cause any damage to the network and are capable enough to put the network security to risk and hence may be a cause of high business damage.

Threats can include various types of viruses, trojans, back doors so as to outright attacks from the hackers. As the majority threats involve multiple exploits so the term blended threat is more accurate when we refer to such attacks.

Types of Threats in Blogging Sites

In 2012, Roger A. Grimes a columnist enlisted these five as common security threats: Social Engineered Trojans, Advanced Persistent Threats, Phishing, Unpatched Software (such as Java, Adobe Reader, Flash), Network traveling worms.

But with the advancement in technology and the use of internet in each and every field lead to more threats and in 2016, Bob Gourley shared a video that contained comments about the security and protection technologies regarding the emerging threats to cyber security and their implications. That video talked about two major aspects that were emerging at that time first Internet of things and second Explosion of data. Today, the list of cyber threats could be seen in other way.

Injection Attacks

Injection attacks falls into the category of those attack vectors that makes the attack capable of injecting not trusted input into the source code. These injected inputs afterwards get processed by the interpreter as a query or command during the execution phase. These attacks are the most dangerous ones for web applications. These may cause data loss, data theft, denial of service and many other problems.

These injection attacks are a major concern in web security. It allows the attacker to attack the program from inside rather than from outside. SQL injection, cross site scripting these kind of attacks falls into the category of injection attacks. These are not only dangerous but are widespread in most of the legal applications. But for these attacks many software applications are present to prevent the system from damage.

SQL Injection

SQL injection is the most common type of attacking technique where the attacker injects the code into the program, query onto a system to execute distant commands. This attack may destroy your database. In this attack placement of malicious program is done between the code. The main purpose of this attack is to manipulate the database or to extract the data. This is used to attack the data-driven applications. Therefore, SQL injection may cause adverse affect on business too. By influencing an SQL Injection, in good circumstances, an intruder can use it to attack web applications. It can affect authentication and authorization mechanisms and intruder can retrieve the contents of an entire database. It can also be used to add, modify and delete records in a database. And give opportunity to the attacker to unauthorized access to sensitive data which may include information regarding customer, personally identifiable information, property information and much more sensitive information (Halfond et al., 2006).

Code Injection

Code injection is the malicious introduction of code into a system. The code injected in the application is capable of intruding database integrity. It can also create privacy, security issues. It can also change data and because of this even data correctness comes into picture. It is also done with the intention to steal data. It also can take control over the bypass access and authentication control. Code injection attacks can multitude applications that are based on user input for execution. Even the SQL injection also falls into the category of code injection. Other types of code injection are script injection, shell injection and dynamic evaluation. It is used to alter the data to give false data. Code injection attacks are not easy to find. There are many solutions that have been developed to find these for both architecture and application. Some of the examples are parameterization, input validation, addition of extra layer of protection, privilege setting for different actions, and many more (Vogt et al., 2007).

Cross Site Scripting

Cross site scripting is also an injection attack. In this type of attack the attacker adds malicious data into the content from other trusted sites. Cross-site scripting attacks takes place when an unreliable source is licensed to inject its own code into an application or web application. The malicious code is added with dynamic content sent to end browser. There are three different types of XSS stored, reflected and

DOM based XSS. Different methods are present to prevent this attack one of the methods is escaping user input, sanitizing user input, input validation (Moore & Clayton, 2007).

Phishing Attack

A Phishing attack is a security attack that tries to gain delicate, private information. Such kinds of attacks are basically done where authentication is needed such as credit card information, username and password credentials. Cyber attackers also use social engineering to influence end users for performing certain action such as clicking on a malicious link or file or some site or attackers tends to extract personal information from users data. This may cause risk to both individuals and organizations. Any kind of data is useful and sensitive; rather it is organizational data or personal data. In addition, some phishing attacks can manipulate organizations data to trick the targets into revealing sensitive information. Attackers mostly targets information regarding user's bank details, card details, company data and any sensitive information that can be important for others (Owens & Matthews, 2008).

Brute Force

Brute force attack is a best way to enter to a site or application that is being protected by password. It is a method which works in a regressive manner until the attacker gets the valid combination. Therefore brute force attack is a repetitive attack scenario. This is a computational method which is not used by common users. These methods are used by hackers and attackers to obtain valid combination. The main motive of attacker is to get illegal access and to steal valuable data. There are some precautionary measures that can be taken to prevent such attack scenario. These measures are password complexity and its length, limit login attempts, using CAPTCHA, cloudflare, two factor authentication and others (Han et al., 2002).

Backdoor Attack

A backdoor is kind of a virus that nullifies normal authentication procedural steps to start an application. This result, distant access to the resources within a system and application example file servers and databases. This makes perpetrators capable of remotely issuing system commands and upgrade malware. Backdoor installation is attained by taking lead with the help of vulnerable parts of a web application. Once installed, it becomes very difficult to detect as files tend to arrange them in a jumbled manner. These webserver backdoor are used for many malicious activities such as Data theft, Server hijacking, Advanced persistent threat (APT) assaults, launch of distributed denial of service (DDoS) attacks, Web-site defacing, Infecting website visitors, watering hole attacks.

Man in the Middle (MITM)

Man-in-the-middle attack is a kind of eavesdropping activity. Man in the middle attack is also known as a fire brigade attack. In this communication between two users is checked and changed by an uncertified client. Mostly, the attacker tends to eavesdrops and snoop by obstructing the common key message interchange and resend the message. In this process, the communication between two parties tends to be normal. This normal scenario didn't confuse the sender if the message transmitted is changed or not and if it is transmitted to the receiver or to the attacker. Therefore, the attacker controls the whole communication (Callegati et al., 2009).

SPAMMING TOOLS

XRumer

XRumer is a software made for spamming online forums and comment sections of an website. It was created by BotmasterLabs and released in the market as the program for SEO (Search Engine Optimization). This tool is able to register and write posts in the forums which is referred as forum spamming, which in turn boosts the search engine rankings. The most commonly used security techniques that most websites and blogs follow in order to detect automated spam are account registration, CAPTCHAs, e-mail verification, client detection, but this tool is capable enough to bypass all these security techniques.

This tool is smart enough as it make use of SOCKS (which is an internet protocol that helps in exchange of the network packets, using a proxy server, between the client and the server) and HTTP proxies. Hence making the it quite difficult for the sysop to block that particular source IP from which the posts are being shared. Also, this software is quite good at making and posting “Innocent-looking posts” these are generally the kind of the posts in which the questions are being asked which mentions the name of spam product. The example of such a type of comments is “Where can I get so and so product? So this tool first register itself to the forum to make the posts in the form of these innocent-looking questions and then make an another registration to post a spam link as the answer to that previously posted question and this is how the software avoids suspicions of the sysop. The side-effect of these types of posts in that that such types of posts increases the product’s rank on the search engine (such as Google, Yahoo, Bing etc.) without falling into conflict of the forums posting rules (Shin et al., 2011).

The tool is able to gather and understand AI (Artificial Intelligence) questions (questions like “What is 2+3?” “What is 4*2?” such types of questions are really common nowadays on the website security checks and are the replacement of CAPTCHA solving). Also with the advancement in technology this tool is becoming even smarter as the latest version of this tool is able to collect such security questions from the multiple sources and hence increasing its efficiency in defeating such types of questions. Here, it is also included in this tool which automatically parse the results from the search engines for the blogs and forums that can be used as the target for the XRumer application.

According to a British Technology news “The Register” (October 2008), XRumer is capable enough to defeat CAPTCHA of Gmail and Hotmail. This way after defeating this software can create accounts on these free email services and them make almost unlimited registrations on the community forums and other web sites and cause spamming. But this was only possible till these services did not change their CAPTCHA formats. So, now the users of XRumer have to use some external captcha services in order to solve the CAPTCHA on these services.

This is a great challenge for the sysops (from administrators and Web Masters) to detect these XRumer users and block so as to maintain the forums terms of services. The easiest method to deal with such types of the XRumer is to verify and approve the posts being made by the new users before it appear to the other users and visitors of the forum and if detected as spam then the XRumer will be detected and hence the IP can be blocked and kept in records. In this way if again the post in received from the same IP then it means some black-hat user of XRumer is there and this time the post will be deleted before it appears to the user.

Visual Web Ripper

Visual web ripper is a strong visual tool that is used for computerised web harvesting, web scrapping and this is also used for extraction of content from the web. This tool moves and scans all the information that is present in a website – the content structure of website as well as the search results. This is used when one needs to extract content from the websites. This tool targets the data extracts it and then send content in structured data in XML files, databases or CSV files (Haddaway, 2015).

Browser Automation Studio

Browser Automation Studio deals with creation of web applications and allows user to swiftly make applications using http client, browser, email client, and different libraries. In this Programming knowledge may be required but skills are not necessary. Major application types are spammers, uploaders, parsers, apps for the social networks, creation of posters. Browser Automation Studio supports arbitrary JavaScript execution. Projects that are compiled using BAS are independent, feasible. These do not need any other software installed on your laptops including BAS. Software operates like macro recorder: all actions that a user makes are recorded and can be played or edited afterwards (Semenov, 2013).

Integromat

It is a very strong tool that can be used manually and is the most advanced and experience based online automation platform. It is capable enough to connect applications, transfer and transform data. It works automatically and there is no user intervention needed to make this tool work. It gives direct support to the application and services with the help of HTTP/SOAP and JSON modules the user can easily connect to any of the web services. Hence allowing the user to virtually automate the entire work with just a few lines of code.

The user can also create its own application through the developer platform on this platform. So it is a quite robust tool available online and easy to use and handle. It gives cutting edge feature which makes the user capable to create its own professional integrations (Hughes et al., 2017).

Comment Anywhere

Comment anywhere is basically a program that will search the search engine for the relevant pages that suits or are similar to the search made by the user as per the user's product description, then help the user leave a comment on such web pages. It's main purpose is to save time and money which the advertisers spend in order to get the response and revenue by advertising the content and getting the positive user response.

This tool makes use of various search engines (like Google, Bing, Yahoo) so that it can cover all the relevant content as per the SEO ranking from on various search engines to make the work even more faster. This way the user can define various keyword to search on the search engines that relate to the business or the product and the tool will search on the global net for these pages and will comment automatically.

Figure 1. Block diagram for form spamming attack scenario

DEVELOPED ATTACK SCENARIO FOR FORM SPAMMING

As shown in the figure 1 is the block diagram for the attack scenario, that how the attacker attacks various vulnerable sites on the global network. The attacker first finds the vulnerabilities in the websites then with the help of various ML (machine learning algorithms) analyse the data and find out all the website on the search engine with the specific set of vulnerabilities.

This way the attacker classifies the various data as per the vulnerabilities. Then the attacker designs certain bots depending on the attack to be made on these websites in the list of vulnerabilities. Once these bots are being made then the attacker is all set and ready to fulfil its desired purpose which can be creation of fake accounts in order to post on the forum websites or to waste the opponents server memory and generate high traffic so that the server may collapse and this may further decrease the page rank and visitors to the website. Not only this, but the bots can even help is advertisements and publicity of one's own website thereby increasing the websites SEO (Search Engine Optimization) ranking and hence more revenue generation.

So the main aim of these attacks is to either collapse the opponents website, generating high revenue by increasing SEO ranking, advertising and increasing page clicks or information leak (which is against law and is information security and privacy is a great concern in today's world.)

DEFENSE TECHNIQUES AGAINST SPAMMING ATTACKS

With the advancement of technology we have various websites and portals that allows the user to develop things easily by automating everything. No doubt, this helps in saving the user time and energy as if a user wants to make a website for their business then they simple have to pay on one portal, describe the design (using few options provided) and it's all set and done. The work that use to take months is done in just few minutes and that too without hiring and expert. But, this is the reason why one needs to be more worried when it comes to security because with increasing ease of development various new threats and attacks have came into existence which were not present in earlier days. Can one image that today, globally 75.9% of the email messages are spam and reason to this is that spamming is quite profitable

and the risk involve in doing such activity is much less than the profit one can gain. From this we can conclude that somewhere we need some techniques so that the new spam can be detected and prevented in order to secure the data and reduce this global increase in spamming (Rahman, & Tomar, 2018). So here are a few commonly used and efficient detection and prevention techniques that are used for detecting and preventing spam. These techniques are based on both machine learning and non-machine learning algorithms. Various systems are introduced for automatic classifications as Bayesian classifiers, Support Vector Machine (SVM), Decision Trees, Neural Networks and sample based methods.

Detective Techniques

Link Based Learning Algorithm

It is a link learning and self-training algorithm which involves the use of classifiers and the self-learning capability of these classifiers and the topological dependency on the web graph. The classifier used is first trained with the small training dataset in link learning. The trained classifier is then used to detect and classify the unlabelled data in the data set being collected from various websites (the dataset maybe the IP addresses or the posts being shared or the registers users email). After labelling the data the spamicity value is predicted. This way in the link learning step first the unlabelled data is classified and then the link spamicity of that data is calculated (Geng et al., 2009). This way the largest and smallest samples are converted into labeled ones based upon values of link spamicity (with their predicted tables).

$$Ps(x) = \frac{p_{spam}(x)}{p_{spam}(x)} + p_{normal}(x) \quad (1)$$

$$Ls(h) = \sum_{v \in N(h)} (ps(v)) \times \text{weight}(h, v) / \sum_{v \in N(h)} \text{weight}(h, v) \quad (2)$$

where v, h are the hosts, $\text{weight}(h, v)$ is the weight of host h, v , $\text{weight}(h, v) \in \{1, n, \log(n)\}$, where n is number of hyperlinks between h and v between h and v . $N(h) \in \text{inlink}(h)$ or $\text{outlink}(h)$. $\text{inlink}(h)$ represent the link set of h , and $\text{outlink}(h)$ is the outline set of h .

$$Ls(h) = \sum_{v \in N(h)} (Ps(v) * \text{weight}(h, v)) /$$

Markov Clustering

Markov Cluster Algorithm abbreviated as MCL algorithm was given by Stijn van Dongen at the Centre for Mathematics and Computer Science in Netherlands. This algorithm is a fast and scalable unsupervised graph clustering algorithm based on the simulation of stochastic flow of graphs (Van, 1998).

As mentioned, MCL is an unsupervised graph clustering algorithm, describing this term. Unsupervised learning and clustering are closely related in pattern recognition systems. Graph clustering is the clustering of the graphs in such a way that the vertices of the graph are grouped into clusters taking into consideration the graph's edge structure. The clusters are made in such a way that there few edges

between the clusters and many edges within each cluster and the basic task of the unsupervised learning is to classify the data set into two or multiple classes based on various similarity measures over the given data set, without adopting any theoretical information regarding classification.

AdaBoost Classifier

Freund and Robert Schapiro proposed this machine learning algorithm. To improve the performance of this algorithm the meta algorithm is used in aggregation with other learning algorithms. This AdaBoost classifier (works with the concept of active learning) make use of confidence based label sampling. The classifier is trained, the training is done by variance and the scoring function is obtained, which is further used to classify the data as spam or non-spam. This means that the data one used as the input is classified as spam and non-spam and the function that is used to classify the data as spam is used generated by this training classifier. This way by using this Meta algorithm the training process is improved. The classifier is used in a series of rounds (recursively) $n=1,2,3,\dots,N$, and for each recursive call a distribution of weights $D(n)$ is updated. These weights indicate the importance of each record in the corpus for the classification.

A few more approaches are used for spam detection, these approaches mostly include K-Nearest Neighbour algorithm and pre-classified data sets which serve the purpose of training data (which helps in the learning process). The classification of the posts or messages is done with the help of KNN algorithm based on various set of features. As if one wants to filter out the spam from the mails then firstly the mails are selected from the inbox and then after analysing it, feature extraction is done. The features may include Number of replies, Number of recipients, Size of the message, Number of attachments and soon. Then with the help of KNN algorithm the data classification is done and F-measure is calculated to obtain the results (Ahmed & Abulaish, 2012).

PREVENTIVE TECHNIQUES

Form Validation

Form validation means adding certain check to the input fields in the form, to avoid the user to submit junk data through the forms. This is mainly done by the developer of the form while coding (mainly using JavaScript in HTML or any other client-side language), but nowadays the users are not making the websites from scratch so the online websites have various plug-ins for the same. Also, many websites use third party tools for form validation as Web-Form-Buddy, Parsley etc. Many common web-bots are detected by the form validation but a few very clever pass these form validations too. So, form validation is one of the great way to eliminate the significant amount of form spam.

Data Confirmation Screen

When the form is filled then a data confirmation screen is displayed which shows the copy of the data being entered for submission by the user. If the user is a web-bot, then it will not be able to confirm the data entry and in this way we can prevent from spam.

Use of CAPTCHA

This is one of the most popular way to prevent form spam. It works by generating a random text (generated using server-side languages) or more complex expression (which don't have any specific pattern so that it can be detected by any web-bot) and stored in a session. Then this text or the complex expression is drawn over an image and included in the form and user has to input that text prior to submission. If the text is not valid (which is compared on the server side) then the form is not being submitted (Rahman et al., 2012).

No doubt, this technique was designed considering the fact that it is easy for the user to detect the CAPTCHA, unlike the bots. But this was true in past, now with the advancement in technology and human minds the quick evolution of OCR programs have helped spammers to solve the CAPTCHA.

The Google's new No CAPTCHA or reCAPTCHA simply ask the user to confirm "I am not a robot" and most of the users simply click it and are able to fill the form but a few (for those the google intelligence algorithm is suspicious about) may have to pass the CAPTCHA test. Google's reCAPTCHA is a very powerful anti-spam device which is also helping the public-service to help digitize text, annotate images and build machine learning datasets and help solving hard artificial intelligence (AI) problems.

Honey-Pot

It is again a new technique to detect the spam and filter it out from the rest of the from submissions. This technique relies on the assumption that the spam or the web bots does not recognize CSS (cascading style sheet) and JavaScript. The honey pot is basically a trap in which the spam thinks that it is working in a right way but in actual it's being befooled by using a non-visible field, as the less intelligent bot which automatically fills out the fields prior to from submission will fill all the fields (including those fields which are hidden from the human eyes). As, the result one can detect that an web-bot attack has been made and the following entries are spam (Rahman & Tomar, 2018).

But again this techniques works for only the web-bots that are not able to detect the CSS or JavaScript and fails for those who are able to detect.

IP Filter

In this technique a list is created which stores all the IP addresses from which the spam has already being received, this list is regularly updated with every spam detection. Then this list is used to filter out the requests to the web from. Regular expressions are used for more advanced and flexible IP filtering.

CONCLUSION

As explained in the chapter, even though there are many advantages of web applications specially blogging sites but there are lot of practical issues related to blogging sites security needs to be answered. Similar to any web application, number of security issues confronts blogging applications. In this chapter security mechanism of (Detection methods and prevention methods) web applications from spamming attacks are reviewed, and the primary characteristics and elements of spamming are also examined. It is revealed that these attacks have a severe impact on web applications and the attacks may lead to the

serious problem for search engine optimization. Nearly all key attacks of spamming along with the possible impacts and the available countermeasures have been described.

KEY TERMS AND DEFINITIONS

Click Spam: It is a process of executing clicks on behalf of user without the knowledge of user.

Cloaking: It is a process of providing different versions of a page to the crawlers.

Form Spam: It is a method of submitting web forms with unwanted information.

Link Spamming: The process of posting links on websites, discussion forums, blogs, and other web services that show user comments.

Spamming: It is an exploitation of messaging systems to broadcast unwanted messages.

Threat: The possibility of malicious attempt to damage or disrupt a computer or system.

Vulnerability: It is defined as a defect, imperfection, weakness, or inadequacy of a system.

Cybercrime in Online Gaming

Solers Research Group, USA

Soonhwa Seok

Korea University, South Korea

INTRODUCTION

Video games are readily available on several platforms, including computers, dedicated game consoles, handhelds, and mobile devices. While these games offer rich interactive experiences, their global connectivity is increasingly raising concerns about safety. For example, massively multiplayer online games (MMOs) have been described as breeding grounds for hackers and cybercriminals. Mobile games are also of interest in this connection, because they may expose players to vulnerabilities through unauthorized access to device features. With video games anticipated to grow in popularity and sophistication, it is vital to have a clear understanding of the most current forms of online risks associated with this form of entertainment.

Considerable information on the Internet speaks to cybercrime as it relates to online gaming. However, there does not appear to be much consensus on the extent to which cybercrime has impacted the video game industry and its gamers, to include conflicting views about specific forms of illegal activity. The belief that today's cybercriminals are using virtual currency in online game economies to launder money is one such example. This idea has been presented by some as a serious problem (e.g., Richet, 2013), with the game industry unknowingly being a pawn in online criminal activity. Conversely, others have contended that the premise makes for an interesting story, but that carrying out such an act would be impractical given the challenges involved (e.g., Messner, 2018).

This chapter extends the work of Seok and DaCosta (2019), who examined the online safety practices of video game players and the degree to which they are exposed to online threats, by offering a deeper understanding of the types of cybercrime that affect the video game industry and its players. Although considerable effort was made to capture peer-reviewed materials, the great majority of the content comes from Internet news articles, to include reports and commissioned studies on the video game industry. Finally, online criminal activity is ever changing, with video games in a constant state of technological advancement. Though it is expected that this chapter will be of value to educators, practitioners, researchers, and game developers and publishers, it should by no means be considered an all-inclusive reference, but rather a catalyst for discussion, debate, and future research.

CYBERCRIME IN ONLINE GAMING

Cybercrime is not new to the video game industry (Cook, 2016; Dickson, 2016). Nevertheless, the popularity and prolific growth in the number of online games have produced new opportunities for cybercriminals (Dickson, 2016), who have come to view these games and their players (hereafter referred to as “gamers”) as easy targets for making quick money through a multitude of techniques. Given that the size of the game industry rivals that of the movie industry in terms of gross revenue, and that hacking techniques are anticipated to grow in sophistication, it has been argued (Cook, 2016, 2017) that the potential for increasingly complex and dangerous online threats is a serious problem.

In the subsequent sections of this chapter, data breaches, compromised accounts and stolen data, the theft and sale of in-game items, and money laundering are discussed. Other forms of cybercrime facing the video game industry, such as the highly debated practices of piracy and reverse engineering, are not discussed. Although these threats are also important, this chapter focuses on the most deliberate types of cybercrime impacting the video game industry in recent years.

Data Breaches

At the time of this writing, data breaches seem to have become commonplace, to such an extent that data privacy and online security have become part of the national conversation. Take the two related incidents involving the U.S. Office of Personnel Management (OPM). The OPM reported that in 2015, the personal data of 4.2 million current and former federal government employees were compromised. The data included names, birth dates, home addresses, and Social Security Numbers (SSNs) (OPM, n.d.). Later the same year, the OPM reported that the background investigation records of current, former, and prospective federal employees and contractors had also been compromised. This included the SSNs of 21.5 million individuals (19.7 million of whom had applied for a background investigation; and 1.8 million non-applicants, primarily comprising spouses or co-habitants of the applicants) (OPM, n.d.). Compounding matters, the OPM reported that some of the stolen data also included findings from interviews conducted by background investigators as well as fingerprints (OPM, n.d.).

Even though victims of large data breaches have sometimes been offered identity-theft protection coverage for a few months, or even a few years (in the OPM breach, for example, victims were given coverage through 2026 [OPM, n.d.]), in many cases the data stolen do not expire. That is, while banks and financial institutions can issue new credit cards to mitigate unauthorized purchases, other stolen personal information, such as SSNs, continues to pay dividends to cybercriminals. Four years after the OPM breach, for instance, two people pleaded guilty to using stolen OPM data in identity theft cases (Weiner & Hawkins, 2018), showing the long-term consequences of such incidents.

Regrettably, the OPM breach is by no means the largest to date. The Equifax breach in 2017 resulted in the exposure of 143 million American consumer accounts (FTC.gov, 2017). The data included names, birth dates, addresses, SSNs, and in some instances, driver’s license numbers (FTC.gov, 2017). The credit card numbers of approximately 209,000 and dispute documents (with personal information) of 182,000 consumers were also stolen (FTC.gov, 2017). Further, in 2013 Yahoo admitted that the information of one billion account holders had been stolen (Burgess, 2016). Yahoo later acknowledge that the actual number of compromised accounts was three billion (Burgess, 2017).

While these hacking events specifically targeted government, finance, and telecommunications, such incidents are by no means isolated to a specific sector, and the video game industry is seeing its own share of large-scale occurrences. The most noteworthy is perhaps the PlayStation Network breach in 2011,

in which 77 million accounts were compromised (Paganini, 2016). The attack was so severe that Sony was forced to take the network offline for 23 days (WeLiveSecurity, 2015). Sony later acknowledged (*Daily Mail Reporter*, 2011) that personal information was stolen from each of the 77 million accounts, to include approximately 12,000 encrypted credit card details (WeLiveSecurity, 2015). Many believe that the PlayStation network hack is among the largest and costliest breaches so far. Sony publicly released that the breach resulted in the loss of US\$171 million (WeLiveSecurity, 2015). The PlayStation network breach shows that in addition to life-long consequences to consumers, there are also costs to those ultimately held responsible for safeguarding the data, to include legal implications. GameStop, for instance, reached a settlement agreement in 2018 in a class-action lawsuit for the loss of customers' personal information that occurred over a six-month period from 2016 to 2017 (McParkland, 2018).

Numerous other large breaches have also occurred within the video game industry; however, many have not received the same level of attention as those described thus far. For example, the online game publisher Gamigo was breached in 2012, causing the email addresses and passwords of over 8.2 million accounts to be stolen and publicly leaked (HaveIBeenPwned, n.d.). The same year, the MMO *Heroes of Newerth* was hacked, resulting in the theft of over 8 million accounts, which included the loss of usernames, passwords, and email addresses (HaveIBeenPwned, n.d.). In 2015, the gaming website R2Games was compromised, with 2.1 million accounts made publicly available. The stolen data included usernames, passwords, and email and IP addresses. Over the course of 2016, an additional 11 million and 9 million accounts were found to have been released, bringing the total R2Games incident to more than 22 million accounts (HaveIBeenPwned, n.d.). Finally, 2016 also saw the breach of the MMO *Evony*, in which 29.3 million unique accounts were stolen. The taken data included usernames, passwords, and email and IP addresses (HaveIBeenPwned, n.d.).

In addition to these examples of large-scale confirmed breaches, many alleged hacks cannot be verified (Hunt, 2016). For instance, the 2017 alleged breach against the Chinese gaming site TGBUS is believed to have included the theft of more than 10 million unique accounts, which included usernames, passwords, and email addresses (HaveIBeenPwned, n.d.). Compounding matters, breaches are not necessarily onetime events. In some instances, accounts are hacked over long periods of time. As mentioned, the GameStop breach took place over a six-month period (McParkland, 2018). Valve also revealed in 2015 that 77,000 Steam accounts were compromised over months (Dickson, 2016; Makuch, 2015) using malware that is readily available on black markets for as little as US\$3 (Dickson, 2016).

Compromised Accounts and Stolen Data

In some instances, those involved in the breaches are not focused on monetary gain but want to demonstrate their hacking abilities or expose system vulnerabilities. However, compromised accounts can be sold to other cybercriminals (Rashid, 2013; Trend Micro, 2015, 2016) for many reasons, to include identity theft and fraud (Trend Micro, 2015, 2016). In the case of the OPM breach, the two individuals who pleaded guilty to identity theft were most likely not involved in the original data hacking, but acquired the information from underground websites, such as those often referred to as being part of the dark web (Weiner & Hawkins, 2018). Further, accounts are not solely collected from data breaches; rather, cybercriminals are also using financial sector hacking (Cook, 2016) and social engineering techniques (Rashid, 2013), to include email and spear phishing practices, to steal login credentials (Tompkins, 2017; Trend Micro, 2015, 2016).

As reflected in the discussion on data breaches, game developers and publishers collect various pieces of information from their customers, such as email addresses and payment information (e.g., credit card numbers, PayPal). In addition, they also frequently collect personal information, such as name, birth year, mailing address, and even social media information (Trend Micro, 2015, 2016). Given that there are reports putting the average gamer's age at 33 (ESA, 2018), these account owners are at the prime age to hold and use credit.

It is the sheer amount of accumulated and composite data, as well as the value behind this information, that makes these accounts so attractive to cybercriminals (Rashid, 2013). When coupled with findings that people often use the same passwords for their email, social media, banking, and other important online resources, compromised accounts can hold far-reaching financial implications (Seok & DaCosta, 2014). To make matters worse, data found in stolen accounts may also be mined with the intent of putting lives at risk. That is, social engineering tactics could be employed to determine if account owners hold significant positions in large corporations or government, or have access to important information, such as U.S. intelligence (Rashid, 2013).

The Theft and Sale of In-Game Items

Money can also be illegally made by selling virtual goods. “Duping” is said to be one of the more popular practices of exploiting bugs to illegally duplicate in-game items or currency for later sale (Cimpanu, 2016). However, online games are also intensely played (Cimpanu, 2016; Cook, 2016) to legally amass in-game items (e.g., weapons, armor) or currency that can be exchanged for real-world money (Cook, 2016). The following DFC Intelligence (2010) study, undertaken in cooperation with Live Gamer, helps illustrate the popularity of such sales. Of the 4,816 mostly male U.S. and European gamers surveyed, in-game goods (i.e., items within the game and not the full game itself) were purchased by approximately 60% of those surveyed, with power-up items purchased by nearly 50% of the participants because they perceived the items would offer a gameplay advantage. The sale and trade of legitimately attained in-game items is not illegal (although some consider the practice as cheating, and thus frowned upon), in-game items connected to stolen accounts can be unlawfully sold (Trend Micro, 2015, 2016). In addition, virtual goods can be purchased with linked credit card information associated with stolen accounts. The illegally purchased in-game items can then be transferred to other accounts and/or subsequently sold (Trend Micro, 2015, 2016). The Steam data breach is an example of this, whereby cybercriminals targeted assets to be resold on Steam Trade (Dickson, 2016).

According to *The New York Times*, the sale of in-game items and currency is so profitable that in 2005 approximately 100,000 Chinese video game players were employed by gamers in other countries to farm popular MMOs (Barboza, 2005). Sweatshops have also reportedly emerged, forcing laborers to farm game currency under poor working conditions for long hours and little pay (Cybrary, 2016). For example, China has been accused of using labor camp inmates to mine in-game items (Moore, 2011) that are sold to gamers (John, 2016), with proceeds going back to the prisons (Vincent, 2011).

Money Laundering

Even more troubling is the earnings from these sales have been said to become part of real-world money-laundering schemes (Solon, 2013). The process has been described as working similarly to traditional forms of money laundering, in which legitimate businesses are used to “clean” illegally attained money (Messner, 2018). The car wash money laundering scheme in the AMC drama series *Breaking Bad* has

been offered as an example (see Messner, 2018). The Netflix original *Ozarks* is yet another example, in which a family, in debt to a Mexican drug lord, purchases legitimate businesses to launder drug money into clean, taxable income.

The same concept holds true in the cyber world. Thus, money acquired from criminal activity can be converted into in-game currencies, and then to other digital exchanges, such as Bitcoin (Sheridan, 2018). In the same way that multiple businesses can be used to launder cash, cybercriminals can use a digital currency exchange (DCE) to digitally transfer money several times between online currencies to make money difficult to trace. Messner (2018) offers an example of how money from a stolen PayPal account is transferred to multiple fake PayPal accounts, unknowingly created by victims in the example. A DCE is then used to transfer the money from the PayPal accounts to other accounts and digital currencies (e.g., Bitcoin). The money may be exchanged even further, to online gaming currency, such as *World of Warcraft* (WoW) gold coins or Linden dollars (the currency used in *Second Life*). Such currency, in turn, could be shared between multiple gamers and then exchanged again (by the respective individuals) to other online currencies.

Even if the fees associated with using a DCE could make it costly to perform multiple transactions, the example demonstrates how online gaming currency could be used to launder money. Nevertheless Messner (2018) points out how such actions lack practicality, especially if millions of dollars need to be laundered, because too many things could go wrong. For example, in addition to losing money in each transaction (because of the fees), there are opportunities to be cheated in the exchanges, the laundering might be detected, and a game developer might notice unusually large transactions, confiscating the currency and/or disabling accounts. This is plausible because, as discussed in Messner (2018), USD\$10,000 would represent a shocking amount of in-game currency. So, while the idea of laundering money using MMO worlds and the like is an interesting one, and might work on a small scale, Messner (2018) illustrates how pulling off such an effort on a significantly larger scale would be difficult.

Money-laundering claims have been no less supported, however. The 2013 report released by the United Nations Office on Drugs and Crime found that MMOs were among the most effective ways in which cybercriminals launder money because of the growth in online game currency systems and economies (Richet, 2013). Games supposedly used in money-laundering schemes have included *FIFA*, *Final Fantasy*, *Grand Theft Auto 5*, *Minecraft*, *Star Wars Online* (*The Old Republic* or *Battlefront* not specified), and *WoW* (Sheridan, 2018). Mobile games have also been identified, to include *Clash of Clans*, *Clash Royale*, and *Marvel Contest of Champions* (Ciaccia, 2018).

The aforementioned mobile games suggest that cybercriminals may be using microtransactions to launder money that might otherwise be detected in more traditional MMOs. As further discussed in Messner (2018), however, the practicality of doing so is also in question, because the game's developer or publisher would have to be involved. Furthermore, for such illegal activity to go undetected, the microtransactions would have to come from gamers who are geographically separated, and who are using unique devices and payment methods, because millions of microtransactions from only a handful of sources would otherwise be detected with payment providers. In addition, games would have to be popular, because unpopular titles would not attract the number of microtransactions needed to launder large amounts of money (Messner, 2018).

While the matter of money laundering in online game currency systems is still being debated, funds from these schemes are said to fuel other forms of illegal activities, such as distributed-denial-of-service (DDoS) attacks. One such example is said to be (Cybrary, 2016) the Lizard Squad attack in 2015 that took the PlayStation Network and Xbox Live offline, subsequently preventing gamers from accessing either service (Paganini, 2016). Worse is the claim that this laundering platform is used by terrorist

groups (Kish, 2017). This claim could possibly help explain reports that British and American Intelligence groups have spied on in-game communications within *WoW* and *Second Life*, founded on fears that online gaming worlds could become hotbeds for dangerous activity (Crecente, 2013). That is, these MMO worlds are believed to have been a way for terrorist or criminal networks to do more than move money, to include secretly communicate or plot attacks (Crecente, 2013).

THE ROLE OF THE VIDEO GAME INDUSTRY AND GAMERS IN CYBERCRIME

Just a few years back, the video game industry was perceived as not having fully grasped that it had become the target of cybercriminals exploiting several techniques, to include server vulnerabilities, DDoS attacks, in-game glitches to steal goods (Cimpanu, 2016), and gaming economies to fuel illicit activities. Furthermore, game developers and publishers were perceived as focusing on the hardening of code to prevent piracy and reverse engineering (Dickson, 2016). More recently, it has been suggested that game companies are aware that their game worlds are being used for fraud (Sheridan, 2018). Kabam, for instance, has warned gamers of misuse that may be occurring within *The Hobbit* (Sheridan, 2018). Blizzard closed the *Diablo* auction houses on the grounds that although they offered a convenient and secure environment for trading, they also undermined the game's core play (Atherton, 2015). Finally, Valve has taken steps to implement new security features in the past few years, such as two-factor authentication (McWhertor, 2015).

Gamers Are Partly Responsible for the Increase in Cybercrime

Despite such safety measures, accounts continue to be compromised, partly because many gamers are not believed to be taking advantage of new security features and capabilities (Makuch, 2015). That is, although cybersecurity professionals advocate the use of antivirus, antispyware, and firewall software, to include keeping these types of products up-to-date, gamers have been found to disable or remove security software altogether, because antivirus and related security apps are known to slow down computers, which, in turn, results in lost frame rates, thereby diminishing the gaming experience (Dickson, 2016).

Results of a Google Consumer Survey that polled 500 gamers helps substantiate this attitude. That is, the survey found that 52% of the surveyed gamers did not use security software on their gaming computers, with 36% actively turning this software off if it slowed down their systems (Abel, 2016). Seok and DaCosta (2019) reported similar findings while examining the online safety practices of 182 gamers, revealing that 35% were not regularly updating their antimalware (i.e., antivirus, antispam, antispyware) software. However, in a broader investigation of the online safety practices of 1,092 high school students, Seok and DaCosta (2014) found that 47% inconsistently kept their antimalware software updated or ignored the practice entirely. Overall, this shows that while the Google Consumer Survey suggests gamers are not leveraging security software to their benefit, the problem may be systemic, and not necessarily specific to those who avidly play video games.

In short, it could be argued that gamers are partly responsible for the increase in cybercrime, to include the loss of in-game goods by not only showing continued resistance to cybersecurity practices seen as gaming hindrances (Cybrary, 2016), but also purchasing and (possibly) selling what may be illegally attained in-game items and currency to fuel their competitive need for quick game advancement (Trend Micro, 2015, 2016). Yet, gamers may not realize that their behavior is problematic and their actions are illegal or could lead to criminal activity.

Despite the expectation that young people can circumnavigate today's technology-rich world, it has been contended that the Internet and respective technologies have put young people in situations where they must make decisions that they may not be developmentally ready to make (Miller, Thompson, & Franz, 2009). When viewed alongside the belief that they are one of the fastest groups of adopters of the Internet (Marcum, Ricketts, & Higgins, 2010), young people may be especially predisposed to online dangers.

A study commissioned by the National Crime Agency (2015) found that the average cybercriminal in 2015 was 17 years old, compared to their findings the prior year, showing an average age of 24. The study also revealed that young people (and their parents) do not understand what constitutes a cybercrime or the consequences of such. Overall, the data from the National Crime Agency study help support the position that gamers may view their actions as nothing more than an extension of their regular gameplay (Trend Micro, 2016), and not a criminal activity. Granted, it is difficult to conceive that stealing a virtual weapon from another gamer in an MMO could result in criminal charges. This mindset, however, has in part contributed to a lack of regulation on the matter, and added to the difficulty of enacting real-world legislation and, subsequently, real-world consequences (i.e., fines, imprisonment) of activities that take place in a virtual world (Jiang, 2011).

Game Developers and Publishers Are Assisting in the Prosecution of Gamers

Game developers and publishers are assisting the courts in prosecuting players. In Japan, for example, Nexon cooperated with the authorities in the arrests of three gamers for obstruction of business due to their alleged role in creating and selling 37 kinds of cheats for *Sudden Attack*, believed to have netted the perpetrators US\$78,621 (Ashcraft, 2014). Blizzard helped convict two gamers allegedly responsible for fencing stolen in-game items from *Diablo II*, viewed by the courts as felony-level theft (Atherton, 2015). Similarly, Epic Games reportedly took two YouTubers to federal court over their alleged involvement in the use of aimbots to hack the *Fortnite* game, selling their cheats for as much as \$300 (Good, 2018).

South Korea has also criminalized the creation, distribution, and use of online game cheats, sentencing those convicted with up to five years in prison and \$43,000 in fines (Chalk, 2016). In June 2017, the country also criminalized other forms of cheating, to include “boosting” (playing while using another person's account to increase the other person's rank), punishable by an \$18,000 fine and suspended two-year prison sentence (Carpenter, 2018).

FUTURE RESEARCH DIRECTIONS

One does not have to go far to find online sources that claim the value of the video game industry is appraised at over USD100 billion. These enormous sums have attracted unwanted attention, fueling cybercrime and a criminal industry said to be valued at USD50 billion annually (Deakin University, 2017). While it can be argued that video game developers and publishers have been plagued by criminal activity since the industry's beginnings, with early concerns centered on piracy and reverse engineering, the global connectivity of today's games raises more serious concerns, including online safety. That is, as the video game industry continues to evolve, moving away from physical media to cloud-based services, and the importance and value of in-game assets continue to grow, cyber threats are anticipated to worsen. For example, the growing number of data breaches alone shows the severity of the problem,

underscoring the importance for game developers and publishers to actively address these new forms of cybercrime head-on.

Also, worrisome, video game companies are not the only targets; cybercriminals also have their sights on gamers. While it is still unclear how much gamers contribute to cybercrime, and what roles they play, it is clear, however, that young people's interest in this form of entertainment is growing, as reflected in the number of console sales. Figures made available in March of 2018, for example, revealed that the PS4, Xbox One, and Switch had sold 75.28, 36.03, and 14.46 million units to date, respectively (D'Angelo, 2018). Furthermore, the belief that gamers may not be aware that their actions are problematic, but perceive their activities as nothing more than typical gameplay for quick advancement, illustrates the need for cybersecurity-related interventions and training to help gamers understand the threats, their causes, and the respective consequences.

CONCLUSION

At the time of this writing, there does not appear to be a consensus on the extent to which the kinds of cybercrime presented in this chapter have impacted the video game industry and its gamers. But it may be safe to say that online safety is a shared responsibility between the video game industry and the gamer community. Game developers and publishers should take the threats seriously by building better security into games, to advance not only the industry and technology, but to also protect users. At the same time, users have a responsibility for their own actions, to ensure that they are not contributing to today's online criminal activity.

ACKNOWLEDGMENT

The chapter authors would like to acknowledge Joshua Shearer, co-host of the podcast site *Just One Thing Gaming* (<https://itunes.apple.com/us/podcast/just-one-thing-gaming>), for his assistance in reviewing, editing, and offering game-related subject-matter expertise.

KEY TERMS AND DEFINITIONS

Cybercrime: Criminal activity involving computer systems, networks, and/or the internet.

Data Breach: A security incident involving unauthorized access to data.

Mobile Games: Digitally based games mostly played on mobile devices (e.g., smartphone, tablet) (DaCosta, Seok, & Kinsell, 2015).

Money Laundering: The conversion of illegally obtained money to legitimate money and assets using legal businesses and transfer of currencies.

Video Games: Digitally based games typically played on personal computers or dedicated gaming devices, such as game consoles (e.g., Xbox, PlayStation) or handheld game devices (e.g., 3DS, Vita) (DaCosta et al., 2015).

E-Banking Security: Threats, Challenges, Solutions, and Trends

INTRODUCTION

There are several types of banks, such as public, private, corporate, development, investment, among other functions, but all have as an essential prerogative the provision of services related to individuals, companies, industries and government money. They range from lending and financing of real estate and vehicles to significant trade-maintaining transactions in the country.

Based on this importance of the banks, security must be applied in the day-to-day of these institutions, because the virtual world is a dangerous place, and without some security control, the tendency is for there to be attempts to steal local money, at the time of looting, among other situations of danger and threats.

Online banking, electronic banking or e-banking consists of the user achieving the most diverse banking operations that are not made within the physical banking agencies. Generally, such transactions are carried out via the Internet, ranging from bank totem to mobile devices.

It has changed people's behavior over the way they spend money since financial transactions can be carried out with just one click. At first glance, this ease and practicality lure the consumers in the sense that their money is safe in and by the financial institution. However, most banking threats are transparent to customers (Singh et al., 2006). It is difficult to quantify the damage of a cyber attack to any financial institution since the impact is not only economic, but other elements make measurement difficult, such as damage to the image and reputation of organizations, loss of confidence in the institution and the loss of potential customers. Therefore, the cost of a cyber attack for an institution may represent a considerably more significant amount than the amount extracted by the attackers.

Although e-banking has been a reality for several years, it is only after 2004 that the incidents began to be reported (Kolodinsky et al., 2004). As a result, e-banking use has declined since threats are reported, but in recent years it has gained strength due to other factors, such as new cryptographic algorithms.

DOI: 10.4018/978-1-5225-9715-5.ch060

None of this is useful when it is the consumer who agrees to be stolen, and this is what most viruses do. Fraudsters take advantage of the innocence of consumers and their inexperience in information security. At the same speed as security techniques advance, threats about such techniques are created (Carminati et al., 2018).

The damage caused by the frauds reaches values in the order of millions of dollars worldwide every year. All these frauds cause customers embarrassment and a lengthy process of adaptation and high costs for the affected banks (Al-Furiah and Al-Braheem, 2009). This chapter, therefore, presents a landscape on all issues ranging from the threat, the challenges to addressing a viable solution to such a threat, and future security perspectives that can prevent new threats from arising that cannot affect online banking transactions.

This chapter presents the following contributions:

- A new taxonomy for classifying threats to e-banking environments.
- A list of new threats that will be organized within the new taxonomy.
- A discussion of such threats and the challenges to address a solution to these threats.
- A review of some trends on e-banking security mechanisms.

From the above, one can note that scams in e-banking environments are not exhaustive, as with each new day a new threat arises. Proposals such as that in this chapter update state-of-the-art concerning new risks and new mechanisms for protecting banking transactions.

This chapter proposes a new e-banking fraud taxonomy, and it presents several types of frauds classified inside such new taxonomy. After, this chapter discusses the advantages and disadvantages offered by the many types of e-banking security proposals. Afterward, we will summarize the work, making it possible to view challenges, trends and future perspectives.

E-Banking Fraud Taxonomy

This chapter proposes a novel taxonomy on security in banking systems, divided into two parts: the first part consists of an approach that organizes and classifies cyber attacks on banking environments, and a second part is an approach that organizes and categorizes current methods of security against cyber attacks discussed in the first part of the taxonomy.

The evolution of computing and new technologies has changed the way data manipulation and information have undergone various changes. As for money, online banking has emerged to make life easier for people, bringing added convenience and agility to the day-to-day operations of our daily activities. Checking balances, transferring amounts and making purchases over the internet is a reality today, but many people still have a bit of a fear of doing this.

Figure 1 shows target-based cyber attacks. Therefore, the attack can be directed to the client and its devices and applications, to the server that supports the banking service and receives client requests, or attacks on the communication between client and server. Threats directed at client devices or applications are mostly idealized through viruses or their variations and require some form of client acceptance (implicit or explicit). Threats to servers or infrastructure that supports banking services are less frequent but usually, occur through cloned services. Threats over the communication infrastructure between clients and the server usually occur through redirecting the network flow to fake sites.

Figure 1. Taxonomy of e-banking attacks, divided by attack target

Based on the increase in the reporting of scams and losses, the fear becomes even more significant, causing many to isolate themselves from this technology and its facilities. However, with some simple procedures, we can make these operations more reliable.

Figure 2 presents proposed solutions to avoid most attacks fanned in the first part of this taxonomy. Such protections can be divided into physical mechanisms and devices or virtual systems and environments. Banking security by physical means has increased in recent years, as it attempts to individualize access, based on devices that are only in property of the client or based on biomarkers. Virtual security consists of digital systems that create abstraction or security mechanisms over which the client can send their data securely.

However, while banks are committed and invested in protecting their virtual boundaries against known and unknown threats, preserving the full breadth of existing IT infrastructure is not an easy task. The large, dynamic threat environment, coupled with the challenge of improving customer safety habits, gives the fraudsters even more vulnerabilities to attack.

The scenario in which the most diverse financial institutions are inserted is also characterized by the need for well planned, integrated, fast, functional and, above all, secure insurance networks. As you can imagine, managing the network of a large corporation, especially in the financial sector, is a complex task. Based on the above, in this chapter, we will describe and classify the different attacks, security challenges, and trends according to the proposed taxonomy.

E-Banking Threats

ISO/IEC 27002 (ISO/IEC 27003, 2013) defines information security threat as being an agent that may cause an incident in a computer system, likely to result in harm to an organization or individual. Threats can compromise systems by exploiting one or more vulnerabilities, whether technological or social vulnerabilities.

Figure 2. Taxonomy of bank security mechanisms divided into physical and virtual

A threat can result in a security attack or incident and occurs as a result of a threat that exploits one or more vulnerabilities. The attack is the absolute fact caused, generating, in most cases, financial or image damages.

In e-banking, threats can mean financial impacts on individuals and banking organizations, as well as reputation impairment. We outline the critical threat methods and tools that put e-banking services at risk.

Phishing. It is a type of attack that aims to steal electronic credentials or financial information from an individual. Usually employs the use of false pages or links, combined with social engineering. The main methods used are fake e-commerce or e-banking pages, fake links shared on social networks, e-mail messages containing links to malicious code pages or electronic forms that solicit personal or financial data. Regardless of the method used, the attackers try to induce the user to click on malicious links using social or economic appeal messages (Montazer and Yarmohammadi, 2013). Phishing attacks are often used to steal information from online payment systems or e-banking access information. For example, the user may receive an alleged message from his bank requesting an update on his/her registration, under penalty of cancellation of his account and a link of a false electronic form is informed. By completing your information on this form, the data is sent to a malicious third party (Hewamadduna, 2017). Different types of attacks and techniques perform phishing, such as:

- **Malware:** They are programs specifically designed to perform harmful actions and malicious activities on a computer. When installed on your computer, malicious code will have access to sensitive data stored on the device and may perform operations on behalf of users. The main types of malware are Botnets, Keylogger, Screenlogger and Trojan-Banker (Méndez-Garcia et al., 2014). The use of malware to capture user banking information is the most widespread type of attack due to the diversity of malicious code and the full range and potential of device infection.
- **Keylogger:** It is a type of malware capable of capturing and storing user-entered keys on a computer keyboard. Its activation, in many cases, is conditioned to a prior action of the user, such as access to a specific e-commerce site or Internet Banking (Wazid et al., 2013) (Sbai et al., 2018).
- **Screenlogger:** Similar to the keylogger, able to store the position of the cursor and the screen displayed on the monitor, at times when the mouse is clicked, or the region that surrounds the place where the mouse is clicked. It is a method widely used by attackers to capture keys typed by users on virtual keyboards, mainly available on Internet Banking sites (Sbai et al., 2018).
- **Trojan Banker:** Collects user's bank details by installing spyware programs that are activated when Internet Banking sites are accessed. They are often disguised as authentic software, but when run monitor and capture user data.
- **Sniffing:** It is a technique that consists of inspecting the data transmitted in computer networks, through the use of specific programs called sniffers. This technique can be used by attackers to capture sensitive information such as passwords, credit card numbers, and the contents of confidential files that are traveling through insecure or weakly encrypted connections (Muhammad et al., 2016).
- **Social Engineering:** One of the primary methods for obtaining confidential information from users. The fraudster uses social engineering to deceive and persuade potential victims to provide sensitive information or to take action, such as executing malicious code or accessing fake pages. In the context of e-banking, it is combined with the Phishing technique to steal logins, passwords or credit card numbers (Suleimanov et al., 2018).

Man-in-the-Browser (MITB): It is a type of attack similar to MITM, but in this case, a Trojan is used to intercept and manipulate calls between the web browser and security libraries, such as encrypted connections. It is a type of attack challenging to be perceived by ordinary users since it can handle e-banking transactions even when security factors are in use (Alghazo and Latif, 2017).

Man-in-the-Middle (MITM): Attack technique that is based on exploiting existing vulnerabilities in communication between two points. Its focus is on intercepting the traffic resulting from the communication of these two, acting as an intermediary. The intermediate can be inserted transparently or through an infected device (Ngalo et al., 2018). The method called sniffer is used to listen to the network, allowing the capture of desired packets. As an example of devices that can be compromised by MITM, we can mention the home wireless routers.

Pharming: Also known as DNS cache poisoning or DNS spoofing, it is a type of MITM attack that compromises the security of name resolvers on the Internet by introducing false information into the DNS server cache, causing the DNS server to return an incorrect IP to a query a web page, diverting traffic to a malicious computer. One of the primary targets of a DNS Spoofing attack is the home routers and DNS servers of local networks (Hussain et al., 2016). Pharming is widely used as a method for phishing attacks. For example, the user attempting to access your e-banking page will be redirected to a fake page that can be used to collect user data, such as access passwords.

DdoS: Distributed Denial of Service is when a set of computers is used in the attack to de-operate a service, computer, or network connected to the Internet. People or institutions that depend on the affected resources are impaired, as they are unable to access or perform the desired operations as financial transactions, for example (Wahab et al., 2017).

Cross-Channel: It is an advanced attack method in which the fraudster steals the credentials and personal information of a user of a service to commit fraud on an associated channel and account. Cybercriminals use advanced attack techniques to exploit vulnerabilities in a channel to steal personal information from other related channels. This type of attack can be combined with social engineering techniques (Khande and Patil, 2014). In general, such type of attack can use botnets. It consists of infected computer networks that can be controlled remotely to attack other computers or systems. An example of how Botnets can compromise a banking system are DDoS attacks, in which a network of infected computers can trigger a mass attack on a server or network infrastructure of a bank (Sood et al., 2016).

E-Banking Security Challenges

As more and more users use electronic banking for bill payment, wire transfers, and e-commerce, malicious users are eyeing that slice of customers that may be exposed to attacks if banks fail to take preventive measures.

In 2017, Brazil already had 940,000 fully digital accounts in the country, and 76% of Brazilians use internet banking services, thus, just as banks have for years invested in safer coffers to maintain except in today's prime security is a factor of advantage over the competition. In addition to scratching the image of the bank, it is inadmissible for a company to lose space for the competition if it does not have consistent security and also pass this image of confidence.

In this chapter, the challenges and defenses that banks have for security have been classified. The classifications are like "Physics", where these are not included in the system of the bank and the "Virtual", that are in the site/own system of the bank. In many cases, banks use more than one security method to increase efficiency and trust in users' access.

Device Registering: Security method in which the bank recognizes and registers the user equipment (Peotta et al., 2011). Usually, this registration happens physically in the agency or the first virtual access to the account. After this, only equipment registered by the bank has access to the account and its transactions.

One-Time Password Token: A token is an electronic device with the ability to generate passwords based on time synchronization (Wayman et al., 2005). The device has a button, where pressed, will display a numeric key, where the user will use as a password. Generally, this method is used as a second instance of security, shortly after the user enters his/her password. Another form of protection similar to One-time Password Token is the One-Time Password Card (Wayman et al., 2005), which consists of a card containing a table with two fields: sequence number (position) and key number. Each card can provide up to 70 sequential numbers. Its operation consists in the bank requesting the key from some random spot, thus confirming the authenticity of the transaction (O'Gorman, 2003).

Device Identification: In this security feature, information about the device, such as operating system, IP range, cookies, etc., is collected to allow access only to legitimate equipment and also to prevent suspicious access, such as from a country other than user resides (Peotta, 2011).

Biometric Authentication: In this example of authentication, stable body characteristics such as digital, iris, face, and palm are used (Wayman et al., 2005). After scans, these data are compared with those already registered in the system and after that, authorizing or not accessing the site or continuing the banking operation. This method is often used together with the user's password (Von Ahn et al., 2003).

Virtual Keyboards: The use of virtual keyboards for entering bank passwords is a method where the user instead enter the information via a keyboard, will use a keyboard on the computer screen and the mouse for this (Rajarajan, 2014). This method arises to prevent keyloggers from capturing the password entered via the keyboard. Generally, the positions of the letters and numbers that appear on the screen for the user are random, thus avoiding the capture of the password by programs that record the location of the user's mouse (Von Ahn, 2003).

Browser Protection: In this method, the bank itself provides software to protect the user's browser (Peotta, 2011). Usually, this installation happens at the first access to the account and is done automatically and making the user's access impossible without this installation being made.

Digital Certificates: In this method, the digital certificate is a document that proves the identity of a user or company, issued by a certifying entity. At the moment the user accesses the bank's website, this certificate is checked, verifying that the site belongs to the bank (Wayman et al., 2005).

Pass-Phrase: This method differs from the already known password and is widely used as a second authentication method. Passwords are used for access to bank accounts and consist of only one word, containing letters, numbers and symbols and a reduced size. Passwords are phrases that, besides including the same letters, numbers, and symbols of the passwords, can also contain spaces and even a larger quantity of characters, making it difficult to break this information. Generally, pass-phrases are used as a second authentication method (Peotta, 2011), only to confirm the transaction.

Short Message Service: This method consists of a notification to the user who owns the bank account (Peotta, 2011). For each transaction, a message is sent to the owner's cell phone informing about the type of transaction and the value. If the recipient does not recognize the transaction, it is possible to block the card by replying to this message. Some banks also use this method for a second confirmation before the transaction takes effect. The user receives a verification code and will have to enter the code received at the moment the system requests.

CAPTCHA: This is a program, where through tests, be these images, texts or simple mathematical equations can differentiate that humans or machines are doing the access to the site (Von Ahn, 2003). The primary purpose is, if the access to the bank is made by malicious software, this software will not be able to respond to the CAPTCHA test, thus evidencing an attack.

E-Banking Security Trends

The need to remain competitive forces banks to offer new services and amenities. Also, the adoption of new technologies can also bring risks to banking activity. Below we describe some of the challenges we consider essential for E-Banking security:

- **Trust:** One of the highest qualities sought in a financial institution is reliability because it is given custody over immense amounts of values (ISO/IEC 27002, 2013). If a bank suffers an attack and can not defend itself, its image before the users can be compromised.
- **The Resistance of Users:** People are resistant to significant changes by nature. Therefore, users can be resistant to major modifications, resulting in insecurity. We can cite as sudden changes the digital banks (Sood et al., 2016).

- **User:** The development of services for e-banking can be done through software engineering techniques, regulations of sector entities or government agencies among others to ensure security. However, the device used by the user and how it is used can compromise all efforts made. The use of malicious or malware-infected software or Keyloggers can capture sensitive information, weakening security efforts. Another technique that can be used is Social Engineering, which is one of the most difficult to prevent. In order to minimize such vulnerabilities, it is essential to educate the user, use overlapping authentication methods and identity verification mechanisms.
- **DDoS:** Annoyance for not being able to perform a transaction can cause damage to a bank's image, affecting user confidence and causing loss. The DDoS attack directly targets the unavailability of services. This can cause a bank to have several of its services severely affected. For this, there is a need for containment plans and mitigation of the attack.

Trying to attract customers confidence, new technologies and services are proposed. In the financial sector, it is no different — the need to remain competitive and attractive means that banks increase the number of existing solutions and services. One of these is called fintech - companies or startups aimed at the financial and technological sector, with the aim of creating and exploring old services in a remodeled way or even building new services. Examples of Fintechs are Paypal, Nubank, SoFi, and Vérios. Other areas of interest can be cited:

Mobile: With more and more people using smartphones there is a migration of services to these devices, seeking to take advantage of the characteristics of these devices (Peotta, 2011). The availability of secure applications for access to banking services will be a challenge, as the number of users catches the attention of criminals.

Bank 3.0: Taking advantage of the digital niche, digital banks arise as an alternative to physical banks. The main difference lies in their organizational structure. They have a centralized architecture and no branches, however, due to the medium where they are inserted - digital, cover a large area of coverage. As your challenges arise: 1) Need to be reliable and credible; 2) Offer competitive and safe services since the entire business model is developed on the Internet.

Biometry: Biometric identification comes as an alternative to conventional authentication methods (passwords and codes), because it combines several desirable characteristics for security, being: the user can not forget the low cost, reliability, not vulnerable to some social engineering techniques, the speed of authentication. Today, biometrics multispectral image sensors are enabled for encryption and hardware tampering - which protect not only the integrity of the sensor but also the communication between the client and the sensor. It is a feature highly valued by the market since these sensors are five times more accurate and four times faster in ATMs and multibank, with a significant reduction of errors. In general terms, there is a gain regarding performance and interoperability. For this reason, in addition to the financial system, the new line of biometric authentication has been adopted in health, electoral and governmental systems.

BlockChain: It is a technology organized in a decentralized way for the storage and measurement of records. Security is inherited from the various decentralized nodes with the power to issue and authenticate records. Thus, any record to be stored can be verified and validated, not by one but by several bases. This record should only be included in the database if it is authorized by several databases, thus increasing security. Many Fintechs were founded and are dedicated to the study and improvement of the use of Blockchain as Circle of Goldman Sachs, Quorum division of JP Morgan. The main difficulties of its adoption are interoperability, privacy, and encryption.

Artificial Intelligence: Considered as one of the primary resources to modify the operation of the banks, its area of coverage goes through the manipulation of the user experience, automation of tasks, identification of anomalies. There is also the risk that this technology will be used by criminals to create intelligent and dynamic tools to be used in fraud.

Major bankers are already testing (in partnership with mobile operators) payments via NFC (Near Field Communication) with mobile phones. This approach payment technology has been used for years in countries like Japan and Australia, but it is still new in several countries. Contrary to what many consumers imagine, these electronic payment devices take over the same logical and physical security mechanisms used by traditional credit cards. And more than that, they offer additional layers of security, reducing the chances of cloning or illegal purchases by third parties, even if the customer's smartphone has been stolen.

In this area, it is worth mentioning that one of the most significant cybersecurity challenges for the banking sector in 2018 is not to implement the technology, but rather to convince the trader that these disruptive payment methods are safe. And they are.

Another exciting technology of online payments that promises to reduce the rate of thefts is the virtual card. These cards are generated by internet banking (provisional security codes) for use in a single purchase. After that, if someone has access to the data, it will not be able to complete the transaction, since all the encoding has already lost its validity. These new technologies have been redesigning the concept of cybersecurity in the country.

The greater the interaction, however, the higher the risks, since these advances also reach cybercriminals. A market has emerged not only from displays of malicious code but also from complete malware offerings such as a service, threat kits, and attack service providers. Now, intruders can buy or outsource complex highly evasive multi-step attacks with little investment or almost no experience, which reduces the entry barrier of new hackers into the market.

Therefore, layered security should be the strategy for new implementations, i.e., it is essential to use different controls at different points in the process of each transaction. This approach is vital to enabling banks to become even more cyber-resistant: also if a defense is circumvented, there will be others to ensure the integrity of the entire ecosystem.

Multilayer security not only allows banks to eliminate the idea of security as an impediment but also to leverage security as an element that enhances differentiation and business innovation. In this way, banks can adapt more flexibly to competitive and emerging threats and opportunities.

FUTURE PERSPECTIVES

Banking institutions will face significant challenges regarding security and innovation from now on. Every day, a growing number of processes move to the digital world, which implies a change in mentality, business models and therefore also in security measures. Customers, faced with this move, expect to be positively surprised by the services of their banks. This expectation can be translated into four words: multichannel, fluency, simplicity and innovation. Avoiding lengthy, complex processes that depend on the physical presence of the client in a bank branch can even encourage them to demand new banking services. It can be, for example, an integrated application for mobile phones, tablets, smart watches, and wearable devices. Or, who knows, a multi-channel experience that flows smoothly, keeps the client engaged and encourages more frequent interaction with the institution.

The idea of E-Banking has been consolidated for some time, not only by the advance of the Internet but also becoming present with the help of innovation and the technologies used for information security. The eternal paradox of information security is that with every new technology that comes to generate customer convenience, it also produces some trace of vulnerability that at some point will be used by cybercriminals to invade systems, steal or hijack sensitive data. Talking about the future of financial institutions, makes us think about how we evolve in different ways. While for banks targeting Internet Banking, Mobile Banking and even BitCoin are common, we can also associate this evolutionary leap in encryption, digital signature, data protection, Blockchain, and various other security-related terms.

Technological developments have pointed to an increasingly digital future, and financial transactions are being incorporated into our routines as something more simplified and transparent. We can see this reality through payments made with mobile and wearable devices. The financial sector has always been one of the most advanced regarding investment in IT and products and services related to financial transactions, and it is no wonder that the emergence of Banks 3.0 comes from technologies such as cloud computing and cybersecurity.

It is noteworthy that this evolution came from a disruption of paradigms, the rise of digital banks represented one of the biggest challenges for the financial market, where it fostered significant changes in the behavior of its consumers. It is possible to see soon that we will have a significant conceptual change regarding financial institutions, in the era of Banks 3.0, they cease to be banks and become financial assistants, all happening online and with little interference from people or institutions regulatory frameworks.

The significant shift from traditional to digital banking has its base formatted in efficiency and confidence through technology and cybersecurity. A digital banking experience, the essence of the Banks 3.0 concept, will be driven by the most automatic, intelligent and secure delivery of products and services. But to consolidate this new concept of bank information security will be fundamental. CEOs who intend to offer this unique experience, in the future so present, besides understanding about the new business models, processes and technologies that will allow us to evolve to the concept of Bank 3.0, should consolidate the idea that without security investments this will not be possible.

Ultimately, Bank 3.0 needs to be agile enough from a technological, structural and cultural standpoint to allow it to adapt to rapidly changing business and technology environments continually. A significant challenge when integrating so much technology and security, identity and compliance requirements. Therefore, the basics that an organization must consider to be increasingly protected are related to processes, staff, and technology. It consists of the application of measures with different approaches, from operational, administrative, technical or technological, to legal and regulatory issues. Only taking all this into account, an institution will have a full possibility to guarantee its security in the face of the many adversities that currently exist in the corporate environment.

INTRODUCTION

Electronic banking or net banking includes any electronic payment system that permits clients of a bank to make transactions through the bank's internet-enabled website or app. It gives access to the facilities of the banks online if there is a required means for it. It provides various services like funds transfer, payment of bills, checking of account details, online shopping and recharge. E-banking has found its place in daily lives as it works as per the comfort and convenience, provides faster transactions, is cost effective and can be done from anywhere. With these advantages, it is also becoming a centre of attraction for Cyber frauds- online frauds in which a person's account is used to transfer funds for financial gain. The Cyber criminals make easy money by duping users, by methods like phishing, vishing (voice phishing), making people download Trojans and malicious softwares which can provide their credentials to the criminal.

E banking frauds have become the most common kind of Cyber frauds which is gaining high popularity. According to a global survey conducted by FIS, a financial services technology firm, Indians are among the most frequent victims of online banking frauds. (Jain, 2018). In comparison, only 8% of people from Germany reported a fraud followed by 6% in the UK. This scenario demands a high level of security measures using latest technology which the Cyber criminals cannot circumvent.

This paper aims at reviewing all types of banking frauds and the measures which should be taken at the bank as well as user level for maintaining the integrity of the online banking systems. It also studies about current scenario of security that is being implemented by the banks and the potential areas like machine learning and big data analysis which can be used as a tool to combat the plight of this blooming industry. The research also directs towards different cases of frauds globally, their cause and implications. It also provides an insight in the study of fraudulent certificates, the damage it causes, and the suggested certificate transparency phenomenon which can solve this problem.

The main focus of the study is to mention the emerging techniques of security that have the potential to combat this menace of e banking frauds. Certificate transparency, HTTP Security Response Headers Automated Analysis Tools, Behavioural analytics and Big Data can help us build systems that are secure against these attacks.

DOI: 10.4018/978-1-5225-9715-5.ch061

BACKGROUND

Online banking today is so prominent that it is hard to imagine that it was not far ago that this boon came into existence. The beginning of online banking dates back to as early as 1980s when biggest banks in New York started providing their customers home-based services. Customers could access their bank accounts to view statements and pay bills. However, the real breakthrough in internet banking arrived in mid 1990s when internet was acknowledged as a distribution media with great potential. The ease and comfort that this breakthrough brought with itself was commendable and life changing. While this mode of access to the banks and ease of handling the accounts was very convenient and had great potential, people soon realized that this flexibility came at a price. Cyber criminals started considering potential in e-banking to accomplish their vicious motives of financial gains by hacking into the systems. Conventional methods of banking frauds soon were replaced now by e-banking frauds. Technological innovations that the banking sector adopted in their quest for growth, in turn opened a gateway for higher levels of cyber risks. It probably introduced new vulnerabilities and complexities into the system. Hackers are now exploiting these loopholes or finding and inventing new technologies to find such vulnerabilities in the banking systems. Various studies and work have been directed towards this critical topic of online banking frauds. Research on this topic includes both the preventive security measures, strengthening the system and the detection of frauds. Banks are constantly working towards the enhancement of security and using various methods to keep the system safe, like encrypted channels for the transactions, two factor authentication and many technologies are being worked upon to secure the system from being exploited by the criminals. Data analysis software are used by examiners to analyse a bank's business data to gain insight into how well internal controls are operating and to find transactions that indicate fraudulent activity or the risk of fraud.

As the security measures on the bank's side tighten so do the advancement in technologies on the hacker's part, as they keep themselves a step ahead. So, this is a need of the hour to work and research in this direction of developing security measures which are technology at par with the technologies used in these cybercrimes. This industry needs more and more cyber security specialist and passionate minds that want to work for the security of online banking systems and find counter measures for all possible attacks on internet banking. Current research aims at reviewing E-banking frauds scenario as a whole, all kinds of attacks on the banking systems, the techniques used behind them and their potential preventions.

CURRENTLY ACTIVE COMMON ATTACKS:

This section first describes the basic model or nature on which the attacks are based on and the study goes on to explain the techniques currently active in deploying the attacks.

NATURE OF ATTACKS:

In this era where the demand for online transactions is growing at a very rapid pace, we need to have complete technical knowledge of the attacks that are committed online and the vulnerabilities they are based on, to provide appropriate security measures and the solution to the growing problem of e-banking frauds. Attacks are escalating their range and complexity to levels that need high technical understanding on the part of its developers. Every attack is determined to defeat in one way or the other, the authenti-

Figure 1

cation systems used by banks to their customers to function. These attacks are based on software tools made by the hackers, applications running on web environments, either in the computer of the victim (malware) or by using various social engineering ways to attract victims to a fake website (Phishing), or on their mobile devices by downloading rogue applications (false APP) (Vilà, 2015)

Figure 1 (Holtz, David, Deus, de Sousa Junior, & Laerte, 2011) explains the main vectors on which the attacking techniques can be based on:

1. **Credential Theft:** This is the most common attack wherein the attackers try to get the user credentials by using malwares or phishing, so as to login as legitimate users and carry out the financial transactions.
2. **Device Control:** It is more complex where the attackers takes full control of a device instead of stealing the credentials from authentication process, and then the user's device itself is used to access the online banking and commit fraud.
3. **Content Manipulation or Man in the Browser Attack:** Occurring in the application layer between the user and the browser. Without the awareness of the user, the attacker can modify and manipulate data.

TECHNIQUES OF ATTACKS:

Most of the attacks are being performed by tools which are nowadays easily available on web. These tools can capture sensitive information and are even capable of replacing the authentic website page with a fake one and the user is made to input on that fake site. Here are some types of common attacks which break the security of the banking systems:

1. **Malwares:** In the present Internet-connected society, e-commerce and e-government (e.g. e-banking and e-payment systems) are being extensively used. Such systems and services can and have been targeted by cyber criminals, and malwares like banking Trojans are popular among financially motivated cybercriminals. For example, a cyber-attack in South Korea allegedly saw 32,000 computers belonging to broadcasting organizations and banks infected with a malware that overwrote the Master Boot Record (MBR) (Kim, Kim, & Park, 2014). Then, in 2013, the Crypto-Locker ransomware reportedly infected around more than three million machines, causing more than 6

million USD worth of damages (Lee, 2013). A more recent case was witnessed in Bangladesh, in 2016, which was a \$951m raid on Bangladesh's central bank where the security systems were penetrated by a criminal gang of hackers with malware that cloned legitimate transactions (All about digital banking fraud prevention).

Malwares can be broadly categorized in aspects like network based and those that aren't network related (Saeed, Campus, Selamat, Ali, & Abuagoub, 2013), and further divided into adware, spyware, virus, worms, backdoors, rootkits and Trojans (Saeed, Campus, Selamat, Ali, & Abuagoub, 2013) (Zolkipli & Jantan, 2011) (Zolkipli & Jantan, 2010) (Kiyavash, Koushanfar, Coleman, & Rodrigues, 2013) (Singh, Singh, & Joseph, 2008) (Salomon, 2010). One important class of malwares that is being extensively used in e banking frauds are trojans.

- a. Trojans have many ways of working, depending on the design they may facilitate/performance capabilities like backdoor, sniffing, spamming etc.

Trojans are considered as one of the most persistent malwares that can evade conventional firewall and antivirus capabilities over a noteworthy period allowing attackers to harvest sensitive information. (Hutchins, Clopp, & M. Amin, 2011)

They pose to be one of the most major threats for the security of e-banking because they are purposely developed to execute frauds in banking systems. The banking Malware (Trojan) is a code that is installed on the user's computer using standard techniques of computer viruses and worms, for capturing data (including information of authentication and user operation and sensitive information like credit card details) exchanged by the user and his bank when the victim uses internet banking. The most fundamental are the "key loggers" that gather, record, read the user's keystrokes or capture images even displayed on the screen when the user operates the banking website (Vilà, 2015). The key loggers keep a track of user's activities on the website.

The Malicious codes continue specializing. Banker Trojans are modified exclusively for banks, changing the look of your real website, by superimposing a fake window when the user accesses the online service of your bank. The overlay looks alike to the legitimate website so that the user enters information authentication codes in it, believing that they are giving the details in the real website. One of the biggest threats that banks are presently facing is the SSL invading Trojan Horses which bypass the secure and authenticated tunnel mechanisms that are the safety backbone of today's internet banking and financial institutions. Trojan horses that the hackers have lately devised have become more complicated as banks have increased their online security measures. Earlier, such malwares could just take usernames and passwords for specific banks, but the hacker had to manually access the compromised account to withdraw funds. Cyber Criminals have now come up with exceptionally sophisticated tools in order to hijack money from the online banking systems.

2. **Man-In-The-Middle Attack:** Normally, the hacker who may control network routers or switches, Wi-Fi access points, and/or DNS is capable to lure the users by disguising their identity (e.g., through DNS poisoning) and it appears as if the data was coming from a trusted source. So instead of going to the legitimate website, users don't realize that they actually used the fraudster's website. The information provided by the victim during the session will be captured and sent to

Figure 2.

the attacker, who can then use the information for committing financial frauds. These attacks can be done using fraudulent certificates which make the user think that the website they are logging into is secure and legitimate without realizing that the SSL certificate of the attacker's website is fake. (Georgiev, et al.)

Figure 2 describes the scenario of a man in the middle attack where the first case depicts the normal flow of information between the server and the client and the second case explains the attack where the invader sits between the client and the server and all the information flows through him.

3. **Brute Force Attacks:** This is a technique where the attacker, with the help of a software tries to break the security and gain access to messages, user ID's, and passwords. In brute force attacks, automated softwares are used to generate many guesses to reach the desired data. It is a kind of trial-and-error method for guessing the passwords of the victims.
4. **Phishing:** It is a deceiving technique which involves social engineering (that refers to psychological manipulation of people into performing some actions or revealing confidential information) and technical subterfuge (Security engineering: a guide to building dependable distributed systems (2nd ed.), 2008). Sensitive information such as usernames, passwords, credit and debit card details are retrieved, as a legitimate looking email or website turns out actually to be a spoof. Victims of this fraud are typically cajoled by certain sources which purports to be genuine such as social websites, auction websites, banks, online payment platforms (safe-browsing-protecting-web-users-for.html,n.d.). Phishers have started Using Encryption to Fool Victims from July 2018, when Google began labelling non-HTTPS websites as "Non-Secure" in the Chrome browser as HTTPS indicates secured interaction between a browser and the website that the user is surfing. HTTPS is recommended on the websites that include online sales or password-protected accounts. Phishing Activity Trends Report, 2nd Quarter 2018 by APWG. APWG member Mark Monitor observed rise in the number of phishing that aimed web mail providers, soaring to 21 percent of all phishing attacks in 2Q 2018, up from 18.7 percent in 1Q 2018 (APWG Phishing Attack Trends Reports, October 20, 2018.).

5. **Fraudulent Certificates:** Fraudsters create sites mimicking the original websites by deceptively issued security certificates to dupe customers into offering over their details (Fake-banking-sites-wrongly-issued-with-authentication-certificates.html, n.d.). Cybercriminals can now steal money by taking gain of the one safety measure every Internet user has been taught to trust: the green padlock in web browsers. These padlocks are supposed to indicate a reliable digital certificate is in use, but now bad actors can attain them for free. The posting of fraudulent certificates does not essentially mean that the entitled operator or certifying agent was involved in illegitimate activity. They may have been shaped and used without the operator's consent or the certifying agent of the certificate (www.ams.usda.gov/services/enforcement/organic/fraudulent-certificates, n.d.). This deceiving technique is taken care of, by the Google's Certificate Transparency project which has been discussed further in the article.

Presently online banking frauds tops the cybercrime lists in many countries worldwide. So, it is a critical time that our banking security and authentication techniques should be at par, in fact a step ahead of the sophisticated tools and technologies the cyber criminals have been developing to crack our systems. The E-banking systems should have efficient security procedures which are able to identify users precisely and then permit the transactions, thus extenuating fraud. Two main factors of the identification schemes: unique secret information earlier shared by the customer and the bank "passwords" and exclusive characteristics of the device which is required to access the service "device fingerprinting" (Khrais, 2015). But, if any of these is compromised, the whole security system would be compromised.

The next section aims at discussing the technologies incorporated by the banks for online security which is followed by the emerging security techniques contemporaneous with the attacks.

SECURITY TECHNIQUES CURRENTLY BEING ADOPTED BY THE BANKS:

Several security layers, consisting of diverse parallel solutions and mechanisms which aim at protecting the banking application and the user's data, providing confidentiality, authentication and authorization.

1. **CAPTCHA (Hasan, 2016):** Completely Automated Public Turing test to state Computers and Humans separately, is a technique employed in some banking systems whose aim is to render bots by generating and rating tests that humans can clear but existing computer programs cannot. Several CAPTCHAs have been developed in recent times. Some are created on Optical Character Recognition (OCR) such as a text CAPTCHA, whereas others are created on Non-Optical Character Recognition (Non-OCR) which requires multimedia, such as voice and video. Some types of CAPTCHAs have been cracked by new bot programs. For example, a text CAPTCHA can be wrecked by using the appliance of segmentation letters. Even though this mechanism proposes fine security and confines automatic cataloguing to web services, some CAPTCHAs have several flaws which allow hackers to penetrate the CAPTCHA mechanism.
2. **Two Factor Authentication:** For any online banking, the main access control mechanism through Internet has been principally user name and password (M, 2017). This simple, single factor authentication has become insufficient in the face of increased cyber fraud activities in current years. The alternate mechanism, which is reasonably more secure and extensively adopted, is two-factor authentication. It requires the users to present two unlike evidence to establish their identity. Two-factor authentication is generally referred to as "something a user has and something a user

knows”(Kruegel & Kirda, 2005). Here, “something a user has” usually involves hardware or software that provides the bank users with an electronically generated passcode or digital certificate. Each bank user has a unique passcode or digital certificate (Sampangi & Hawkey, 2016). Then, the next factor, “something a user knows,” generally means a private password. Clients should use both factors to give them access to critical resources. Two-factor authentication systems are more secure because it is not easy for hackers to get both the factors.

3. Digital Certificates

- a. SSL (Secure Socket Layer) is the foundation of the Internet protection (what-is-ssl.html, n.d.). It secures website and handles the confidential and sensitive information of the users like credentials by providing critical security, privacy and data integrity. It is important to send the information across the network in an encrypted form, such that only the recipient who is supposed to access can comprehend it, maintaining its integrity. The information is unidentifiable to everyone when an SSL certificate is added to the website and it ensures the security of the important information of the users from phishers, hackers and identity thieves. SSL certificates provide authentication to ensure that the data is being sent to the right server. SSL certificates like EV SSL Certificates, asks for more verification and validation than the common SSL certificates. Extensive checking like verification of legally registered organisations, their address and phone number, ensuring if they have a right to use the domain, authorizing the person ordering the certificate and checking that the organisation is not on any blacklists of the government. Visual cues, like lock icon or a green bar make sure that users of the website feel secured. When a SSL-secured website is accessed by a browser, then web server and browser tries to form an SSL connection using a method called an “SSL Handshake”. User cannot see a Handshaking process as it occurs instantaneously. When a browser accesses a website that is safeguarded by SSL, the browser and the web server institute an SSL connection by means of “SSL Handshake”. ([digicert.com/ssl/n.d.](http://digicert.com/ssl/n.d)) SSL Handshake occurs instantly and is imperceptible to the user. Basically, three keys associate the SSL connection: the public, private, and session keys. Encryption with the public key can only be decrypted with the private key, and vice versa. After the secure connection is created, the session key is used to translate all transmitted data.
- b. The latest version of SSL (3.0) which is known as Transport Layer Security (TLS). Algorithms like 1.0. RSA, AES & SHA1 are used for encryption & decryption of the text. TLS has sturdier message authentication, key-material generation and other encryption algorithms. For instance, TLS provisions pre-shared keys, protected remote passwords, elliptical-curve keys and Kerberos whereas SSL does not. TLS and SSL are not interoperable, but TLS proposes backward compatibility for older devices that are still using SSL. The TLS protocol specification explains two layers. The TLS record protocol provides connection security, and the TLS handshake protocol allows the client and server to validate each other and to exchange security keys before any data is transmitted.

EMERGING SECURITY TECHNIQUES RECOMMENDED FOR BANKS:

1. **Certificate Transparency:** Google's Certificate Transparency project repairs several operational defects in the SSL certificate system, which is the key cryptographic system that triggers all HTTPS connections. These flaws deteriorate the reliability and efficiency of encrypted Internet connections and can compromise acute TLS/SSL mechanisms, including domain confirmation, end-to-end encryption, and the chains of trust established by certificate authorities. If left unrestricted, these faults can enable a wide range of security attacks, like website spoofing, server impersonation, and man-in-the-middle attacks. Certificate Transparency aids in eradicating these errors by providing an open framework for checking and auditing SSL certificates in nearly real time (Laurie, Langley, & Kasper). In detail, Certificate Transparency senses SSL certificates that have been erroneously distributed by a certificate authority or malevolently acquired from an otherwise flawless certificate authority. It also makes it possible to recognize certificate authorities that have gone scoundrel and are maliciously handing out certificates.
2. HTTP Security Response Headers
 - a. HTTP Strict Transport Security (HSTS) is a web safekeeping policy contrivance that aids to protect websites against protocol downgrade outbreaks and cookie hijacking. It allows web servers to assert that web browsers (or other conforming user agents) should interrelate with it using only protected HTTPS links, and never via the apprehensive HTTP protocol. The HSTS Policy is linked by the server to the user agent via a HTTPS response header field termed "Strict-Transport-Security" (en-US/docs/Web/HTTP/Headers/Strict-Transport-Security, n.d.). HSTS Policy agrees on a period of time during which the operator agent should only contact the server securely (Hodges, Jackson, & Barth, 2018). As the HSTS HTTP Header is only renowned when directed over a HTTPS connection, websites can still allow users to network with the website using HTTP, to allow compatibility with non-HTTPS user agents.
 - b. HTTP Public Key Pinning (HPKP) is a safekeeping policy that tells a web client to associate a detailed cryptographic public key with a certain web server to cut the jeopardy of MITM attacks with bogus certificates (Evans, Palmer, & Sleevi, 2015). Web clients such as browsers trust a lot of these CAs, which can all form certificates for arbitrary domain names. If an invader is able to compromise a single CA, they can execute MITM attacks on numerous TLS connections. HPKP can evade this risk for the HTTPS protocol by telling the client which public key fits in to a certain web server. HPKP is a Trust on First Use (TOFU) procedure. (en-US/docs/Web/HTTP/Public_Key_Pinning, n.d.) The first time a web server interacts with a client via a distinct HTTP header which public keys belong to it, the client keeps this information for a given period of time. When the client visits the server again, it believes at least one certificate in the certificate chain to hold a public key whose fingerprint is already known via HPKP. If the server distributes an unknown public key, the client should present a cautionary to the user.
3. Analysis Tools and Big Data (Bhasin, 2016)

The industry is progressively responsive of the need for programmed analysis tools that recognize, and account fraud attempts timely. Solution providers are providing instantaneous transaction screening, third-party screening as well as compliance resolutions.

Data Visualization Tools: These are being used to propose a visual demonstration of multifaceted data configurations and outliers to decipher multidimensional data into evocative pictures or graphics.

Behavioural Analytics: This is helping businesses recognize enemies masked as customers. The data analytics applied by the institutions to understand customer behaviour, preferences, etc. are also serving in the detection of fraudulent activity either in real-time or post mortem. The industry is progressively responsive of the need for programmed analysis tools that recognize, and account fraud attempts timely. Solution providers are providing immediate transaction screening, third-party screening as well as compliance resolutions.

- a. The organization inputs every consumer's transaction history and procedures a comprehensive side-view based on their digital banking behaviour where and when they typically transact, their systematic variety of counter parties, the methods they typically access the bank's systems and the standard size of transactions (NG_Digital_banking_fraud.pdf). This technique is functional both to individual customers and to organizational financial accounts that have multiple authorized users. The profile that the system generates becomes part of the pattern against which every future digital banking transaction is associated to assess whether it matches the customer's well-known patterns of behaviour. This behavioural figures is amplified by a wide range of contextual information variables such as the customer's geolocation, time of day, week and month, the device, web browser and type of webpage that is being observed, the kind of account involved (individual or institutional, for example), the domestic or international destination of any payments, whether the payee is first-hand or previously known, and so on. When distinct transactions are assessed against the risk model, it calculates the probability that the transaction is deceitful based on the explicit conditions in which it takes place and the level to which it deviates from the familiar pattern of behaviour related with that account. Significantly, where some anti-fraud systems analyse transactions by size alone, flagging everything above a certain worth, advanced systems appeal on a wider range of contextual information to emphasis the search.
- b. Most anti-fraud systems that employ advanced analytics, incorporating comprehensive user profiles, cannot function in real time and risk failing to sense fraudulent activity quickly enough to avert losses. The efficacy of technology-based anti-fraud systems depends crucially on their capacity to operate in real time, so that suspicious activity can be flagged instantly and transactions blocked. However, the most advanced anti-fraud systems employ Big Data technology, permitting them to apply the advanced analytical techniques to vast volumes of transactions in real time.
- c. **SIEM** (security information and event management) software is installed in order to tackle today's sophisticated cyberattacks. Organizations need to have access to analytics-driven SIEMs that utilises a big data platform that is augmented for machine data with innovative analytics, threat exposure, monitoring tools, incident response tools and threat intelligence.
4. **Deep Learning (Bhasin, 2016; Digital Banking Fraud: Best Practice for Technology-Based Prevention):** It is a technique that teaches computers to do what naturally comes to humans i.e learn by example. The deep learning works on complex algorithms which are based on building hierarchy of abstraction in which each layer is created by the knowledge gained by previous layer. Each algorithm in the hierarchy applies a nonlinear transformation on its input and uses what the knowledge to create a statistical model as output. Iterations will continue until the output reaches an acceptable level of accuracy. In a deep learning process, the data scientist identifies the relevant data sets and prepares them for analysis, chooses and then trains the algorithm on large amount of labelled data and then finally tests the model's performance against unlabelled data.

Internet payment companies providing replacements to traditional money transmission methods are using deep learning, this new method to machine learning and artificial intelligence that is good at recognizing complex patterns and features of cybercrime and online fraud. It can be used to detect suspicious users and thus can help in preventing the potential frauds.

The above technologies should be employed by every bank to keep in pace with the growing technologies behind the attacks. But the security of banking systems is also the responsibility of the users along with the banks and therefore requires knowledge of the topic on the part of the individuals. Having studied about the security measures employed at the bank level, we will discuss the measures that should be taken by the users for the secure handling of online transactions in the following section, as complete awareness at the client's part is also required.

MEASURES THAT SHOULD BE TAKEN WHILE DEALING WITH ONLINE TRANSACTIONS:

1. **Check the Activity of Your Online Account Regularly:** This may be the single most effective strategy one can employ to secure the account and keep a check on any unauthorized access.
2. **Create a Strong and Uncrackable Password:** Passwords should always be a combination of uppercase, lowercase alphabets, numbers and special characters. They should not be kept on basic personal information which can be easily guessed and cracked. Also they should be changed regularly.
3. The passwords, PIN, and other account details should not be shared with anyone and should be memorized.
4. **Never Click on Suspicious Links or Links Embedded in Mails:** It is easy for scammers to set up convincing emails. The users should never click on links contained in mails received from banks. The right way is to type in the bank's website in your browser and navigate from there.
5. **The Users Should Never Give any Account Information Over the Phone or on Mail:** Banks never ask for this information and the calls and mails could be from fraudsters.
6. **One Should Always use Anti-Virus Protection Software, Firewalls and Spyware Blockers and Keep the Softwares Updated:** by keeping these basic computer protections up to date, one can greatly reduce the vulnerabilities of being attacked by the hackers.
7. **Online Banking Should Only be Used on Secure Wi-Fi Networks:** Banking on public networks is not at all recommendable. The low level of security on such networks can be a prime target for attacks.
8. **Always Check for Secure Connections:** While browsing a bank's website and making online transactions, one should be careful of secure connections, if the web address starts from https, it is considered safe.
9. **Always Use Official Banking Applications:** These legitimate apps are tested to ensure the data is secure.
10. **Always Log Out When the Session is Complete:** This mitigates the chances of leaking the information, especially when you are in a public space where not logging off from online account can lead someone else to have access to the sensitive information.

CONCLUSION

4

Cyber-fraud has become a worldwide illicit industry comprising skilled and trained criminals with extreme technological knowledge and access to very sophisticated tools along with the awareness of how financial system works. The level of complexity of frauds is increasing day by day with involvement of more and more people due to which advancement of prevention technologies and security also needs to be evolved. It was discussed how the implementation of SSL certificates, HTTP Security Response Header and Certificate Transparency are most advanced methods to make the E-banking websites secure. The most progressive anti-fraud systems on the market today are using Big Data technology to apply innovative analytical models in real time, giving banks the ability to recognize and block apprehensive activity as it occurs. Machine learning has also become a crucial implement in advanced anti-fraud systems and a prominent growth in its role is going to be witnessed in the upcoming times. New generations of risk modelling, using machine-learning systems that have been developed to spot fraudulent transactions amid vast volumes of banking data, are starting to replace the statistical, probability-based approach that has been used up to now.

Many of the frauds we see today are also happening at user end where the hackers trick the users into giving their personal information and sensitive data which is used to an advantage of the attacker for committing fraud. So, the banks need to employ online banking systems whose security is as user independent as possible. Security measures at both the levels are mandatory for keeping this issue of frauds in check. Looking at this perspective, computer experts are working on creating anti-fraud systems that are more sensitive to the complex patterns of fraud and collusion that are a feature of professionally executed Cyber-frauds. Sensitive systems will allow banks to create an improved equilibrium between detecting frauds and allowing customers to carry out their transactions unhindered.

Improvement in technology and development of innovative techniques based on machine learning can give banks potential access to sophisticated systems that are more effective and more efficient, thus mitigating the chances of frauds.

KEY TERMS AND DEFINITIONS

CAPTCHA: Completely automated public Turing test to state computers and humans separately is a technique implemented in some banking systems whose aim is to render bots by creating and rating tests that humans can clear but existing computer programs cannot.

Certificate Transparency: Google's certificate transparency project repairs several structural defects in the SSL certificate system, which is the key cryptographic system that triggers all HTTPS connections.

HPKP: It is a safekeeping policy that tells a web client to associate a detailed cryptographic public key with a certain web server to cut the jeopardy of MITM attacks with bogus certificate.

HSTS: It is a web safekeeping policy contrivance that aids to protect websites against protocol downgrade outbreaks and cookie hijacking.

HTTP: It is a web safekeeping policy contrivance that aids to protect websites against protocol downgrade outbreaks and cookie hijacking.

Malware: Malware, or malicious software, is any program or file that is detrimental to a computer operator. Malware comprises computer viruses, worms, Trojan horses and spyware.

Phishing: It is a deceiving technique which involves social engineering (that refers to psychological manipulation of people into performing actions or divulging confidential information) and technical subterfuge.

SIEM: Security information and event management.

SSL: It is the foundation of the Internet protection. It secures website and handles the confidential and sensitive information of the users like credentials by providing critical security, privacy and data integrity.

TLS: The upgraded version of SSLv3.

Tackle the Smart Contract Vulnerabilities

INTRODUCTION

The advent of Blockchain technology led the way towards the development of an electronic contract called Smart Contract. Technically, a smart contract is a computer program that is deployed and running on blockchain they are immutable, public and decentralized (Szabo 1997). The decentralized model of immutable contracts denotes that the execution and output of a contract are validated by each participant in the system so that no single party/participant is in control of the money. That is, no one could force the execution of the contract to release the funds, as this would be made invalid by the other participants in the system. Tampering with smart contracts becomes almost impractical.

BACKGROUND

This section briefly features the nature and the need for smart contracts technology along with its basic properties.

What Are Blockchain and the Smart Contract?

A blockchain is a cryptographic database (ledger) maintained by a network of computers, each of which stores a copy of the most up-to-date version. A blockchain protocol is a set of rules that dictate how the computers in the network, called nodes, should verify new transactions and add them to the database.

A smart contract is an electronic form of conventional contract/agreement deployed and running on the blockchain which executes the terms of the contract automatically without any need of trusted third parties (mediator, court, etc) for the effective implementation.

Figure 1 depicts the sample use case of smart contract in the Business (farmer) to customer model.

Need for the Smart Contract

Traditional transactions are built on trust and, usually, contracts are considered as a symbol for an existing business deal by the contracting parties. Another major problem with the traditional contracts is that they do not provide enough details about the actual transaction process and as a result. Friction with conflicts between the contracting parties is more frequent (alexafana 2016).

The above mentioned problems are addressed effectively by the development of a smart contract. In general from the viewpoint of information technology smart contract is viewed as an online program, in reality, it is a multidisciplinary concept that also concerns finance/business and contract law, each with

DOI: 10.4018/978-1-5225-9715-5.ch062

Figure 1. Farmer to customer transaction using smart contract

the different perspective (Chapter 9: Building a Secure Future, One blockchain at a time 2018). That is, from the viewpoint of business, a smart contract defines how transactions and payments are executed among different accounts. From the viewpoint of contract law, a contract is an agreement between mutually committed parties (Ustbmde 2018). Because of its interdisciplinary nature, development of smart contract needs collaboration between many experts such as business experts, software and information security engineers, lawyers, and bank managers from different domains (He, et al. 2018).

Properties of Smart Contract

Everything that runs on a blockchain required to be immutable and should have the capability to run through multiple nodes without any compromise on integrity. In order to achieve that, smart contract functionality needs to have three things in common:

Deterministic

A deterministic program is the one that gives the exact output every single time for the particular given input. That is, if the output for $5+1$ is 6 then $5+1$ ALWAYS will have 6 as an output (assuming the same base). But, there are numerous moments a program can act in an un-deterministic manner:

Calling Un-Deterministic System Functions

Un-deterministic data resources: If a program receives the data from the un-deterministic data source during runtime then it becomes un-deterministic.

Dynamic Calls: Dynamic calling occurs when a program calls another program in which the target of the call is decided only during execution.

Terminable

In 1936, Alan Turing, a mathematician, deduced using Cantor's Diagonal Problem, that there is no way to predict whether a given program can finish in a time limit or not, this unknown execution time inability is known as the Halting Problem.

In smart contracts, this is an apparent problem because contracts must have the capability to terminate in the given time limit. There are few corrective actions have taken to ensure that the contract does not enter into an endless loop which will drain the resources. To tackle this terminable problem, below mentioned properties are used by smart contracts

Turing Incompleteness: Since Turing, Incomplete blockchain have only limited functionality, for example, to avoid endless loop jumps and/or loops are not allowed.

Step and Fee Meter: A program can plainly keep track of the number of steps it has taken and terminate when a particular step count has been reached. Another method is the Fee meter, where the contracts are executed with a predefined fee and for every instruction execution requires a particular amount of the fee. When the fee spent exceeds the predefined fee the contract gets terminated automatically.

Timer: the predetermined timer is used, If the contract execution exceeds the specified time limit then contract to get aborted externally (Atzei, Bartoletti and Cimoli, SoK: unraveling Bitcoin smart contracts 2018).

Isolated

In a blockchain, almost anyone can upload a smart contract. Because of this feature, the contracts may contain malicious code. So a non-isolated contract may damage the entire system. Hence, isolation of smart contract in the sandbox is very important to save the entire ecosystem from any negative effects (blockgeeks.com, A Deeper Look at Different Smart Contract Platforms 2018).

While smart contracts promise much to consumers, due to its complex properties, interdisciplinary nature and underdevelopment phase, there is a strong possibility of harming the consumer if proper regulation is not in place.

This paper intended to focus on such common vulnerabilities and proposed effective security measures to tackle the potential risks along with the future development area to avoid security risks.

VARIOUS COMMON VULNERABILITIES

This section briefly explains the most common vulnerabilities, which result in huge financial losses in the past few years.

Generally, smart contracts represent a new blockchain attack vector that hackers can compromise by applying other methods that are typical for compromising blockchain technology, including DDoS, eclipse, and various low-level attacks.

Basing on a recent study performed on nearly 1 million Ethereum smart contracts, 34,200 of them were discovered as vulnerable. That surprising number was attained by analyzing trace vulnerabilities of smart contracts including:

- Finding contracts that lock funds indefinitely-Greedy contracts
- Contracts that lack funds carelessly of arbitrary users-Prodical contracts
- Contracts that can be killed by anyone-Suicidal contracts (Han, et al. 2018).

Along with the general logical complexity and novelty associated with programming smart contracts, their immutable nature makes vulnerabilities potentially much more damaging (Curran 2018).

The main blockchain security issues associated with smart contracts relate to possible bugs in source code, a network's virtual machine, the runtime environment for smart contracts, and the blockchain itself. Let's have a closer look at each of these attack vectors.

For easy understanding, the following solidity vulnerable smart contract code has been used throughout the paper as a reference to explain the numerous vulnerabilities.

```
pragma solidity ^0.4.18;
contract Sample_wallet{
// owner variable specify the owner address
// balances variable is used to maintain the users balance
address public owner;
mapping(address=>uint256) balances;

// Constructor for assigning the owner address
function Samplewallet() public {
owner=msg.sender;
}
//Modifier used to check a condition before executing the function
modifier owner_only {
require(msg.sender==owner);
_;
}

// Kill function uses selfdestruct function to kill the contract and send re-
maining ether to specified address
function kill() owner_only public {
selfdestruct(owner);
}
```

```
// Deposit function allows the user to deposit ether to his account
function deposit() public payable {
    balances[msg.sender] += msg.value;

}

// Transfer function is used to transfer ether from the user account to the
specified "to" address
function transfer(address to, uint _token) public {

    require(balances[msg.sender] > 0);
    require(to.call.value(_token)());
    balances[msg.sender] = balances[msg.sender] - _token;
}
}
```

The above vulnerable contract is the simple wallet contract which takes the token (ethereum cryptocurrency) from the user via deposit() function, and allows him to transfer his token to any specified account of his choice by calling transfer() function. It also allows the contract owner to kill the contract at any time by calling kill() function.

Choosing the Platform

There are many smart contract platforms available with various properties which make them unique. There is no “one-size-fits-all” yet. Hence, users have to choose the platform that best suits the functionality requirement of their Dapp(Distributed Application).

Since it's a new technology, all the platforms are still evolving, every platform has its own kind of vulnerabilities. The wrong choice could lead to irreversible stability, scalability, security issues which in turn results in a huge financial loss. So choosing the best fitting platform for the application itself is a challenging task as now.

In Virtual Machines

Each blockchain platform has its own virtual machine/docker to execute the smart contract. That is, each virtual machine/docker has its own set of vulnerabilities, few are universal, few are unique to the virtual machine.

Let's take an example of the most commonly used Ethereum Virtual Machine (EVM) and its vulnerabilities.

EVM is a distributed stack-based computer runtime environment used for Ethereum's smart contracts where all smart contracts of Ethereum-based bloodstains are executed. The most common vulnerabilities of the EVM are as follows:

Short-Address Attack: EVM can accept incorrectly padded arguments, hackers can exploit this vulnerability by sending specifically crafted addresses to potential victims. For instance, during a successful attack on the Coindash ICO in 2017, a modification to the CoindashEthereum address made victims to send their Ether to the hacker’s address (Bryk 2018).

[illegible]

Vulnerabilities in smart contract source code constitute a threat to parties that sign the contract. Because bugs in source code are impossible to fix due to its immutable nature. This risk makes the cybercriminals to discover and exploit code vulnerabilities to steal cryptocurrency or create a new fork, as happened with the DAO attack (DuPont 2017).

The following is a list of few known attacks which can be avoided. The comprehensive list of attacks is provided in the ADDITIONAL READING (Manning 2018) section for reference.

The Overflow Error

An overflow arises when a number gets incremented beyond its maximum value.

Let's see the snippets from solidity:

```
uint8 Value = 255;
```

```
Value++;
```

In Solidity unsigned integer of 8 bit can take value from 0 to 255. So incrementing Value by 1 would lead to an overflow situation which set the Value to 0. Developers must be aware before declaring the variables.

The Underflow Error

The Underflow error, on the other hand, work in the exact opposite direction. Let have a look at another example, uint8 can take values only between 0 and 255.

Consider the following snippets

```
uint8 Value = 0;
```

```
Value--;
```

Decrementing the Value by 1 lead to underflow situation which will set the Value to 255.

The underflow error is more often than the overflow error because it will be somewhat impossible for someone to get the required number of tokens to cause an overflow(blockgeeks.com, Understanding Overflow and Underflow Attacks on Smart Contracts 2018).

Consider this scenario in the above mentioned vulnerable contract. The malicious user is having a balance of 5 tokens, that is, balances[msg.sender]=5. If he calls the transfer() function with _token value as 6.

The code line in the transfer() function balances[msg.sender]=balances[msg.sender]-_token will get executed as balances[msg.sender]=5-6. This subtraction leads to underflow, where the user balances[msg.sender] will be credited with a positive number (2^{256}).

Race Conditions

Race Conditions are a general system's behavior where events do not occur in the planned order. Race Conditions may possibly arise in Smart Contracts, from calling external contracts that take over control flow.

Reentrancy is a kind of Race Conditions, in which some function is called repeatedly before the first function invocation is completed. Scrutinization of external calls, that is, to block concurrent calls in certain functions would be the key solution.

In the above-mentioned vulnerable contract if the user calls the transfer() function, first it checks whether the balances[msg.sender] is greater than zero or not. If yes, then it sends the specified token to the specified "to" address and then deduct the token value from the user.

Say the above contract is in a Sample_wallet.sol file and the malicious user create a Hack.sol file with a Hack contract to exploit the external call.

Tackle the Smart Contract Vulnerabilities

```
contract Hack {
Sample_wallet s;
uint public count;
uint etherValue=5;
function Attacker(address vulnerable) {
s = Sample_wallet(vulnerable);
}

function attack(address _to) {
s.transfer(_to,etherValue);
}

function () payable {
count++;
if (count < 10) {
s.transfer(to,etherValue);
}
}
}
```

In Hack.sol, two primary functions are defined. The first is attack() function that calls the transfer() function of Sample_wallet contract. Now, Sample_wallet contract's transfer() function executes the call() function to send 5 tokens to Hack.sol, that in turn triggers the second function, function() payable{ } of Hack.sol which will call the transfer() function again for 5 tokens. The key point to note here is, the initial transfer() function's call() function is not yet completed, so user balance is still the same irrespective of 5 tokens transferred. So calling transfer() function in the loop will transfer 5 tokens every time without deducting the user balance.

Transaction-Ordering Dependence (TOD)/Front Running is another kind of race condition, which allows one user to benefit from a manipulated transaction order at the cost of another user while the transaction being located in a mempool for a short time.

Timestamp Dependence is one of the conditions that allow Front Running, scrutinization of time-stamp usage in a contract is necessary, especially in cases where transaction time is financially important - such as in a betting contract. Because beware that miners can manipulate the timestamp of the block (blockgeeks.com, How to Audit a Smart Contract 2018).

Programmer/Human Error

Smart contracts development requires a different mentality than developing traditional software. It's more like building a monument that you want to last and remain beautiful for a long time than like building a complex mechanism. Even a minimal bug may lead to irreversible damage.

Developer failures are mostly due to

- Misunderstood the objective
- Making a mistake when implementing that objective

Many of these typical errors may be results in huge sums of locked up funds like with Ethereum's recursive send exploit in the DAO incident or with the Parity wallet (Curran 2018).

In our example, function `SampleWallet()` is deemed to be the constructor, but our contract name is `Sample_Wallet`. So solidity will consider it as a normal function which can be called by anyone. If attacker calls this function he will be the owner of the contract which authorizes the attacker to call `kill()` function to kill the contract and send the entire contract balance to attacker's address.

BEST PRACTICES FOR IMPLEMENTATION

This section covers solutions and best practices to tackle the above-mentioned vulnerabilities.

Platform Selection

It's difficult to compare all the platforms because each platform is meant for a specific purpose, so, it just depends on your needs. It's best to consider the maturity of each platform as that's a good indicator (Smooke 2018). The followings are some indicators which can be considered while choosing the platform

Supports Millions of Users: A platform has to be scalable enough for millions of users to use it. This is especially true for DAPPs that are looking for major acceptance.

Free Usage: The platform should enable users to use it for free for the development purpose. That is, the user should not ask to be paid for the platform to gain the benefits of a Dapp.

Easily Upgradable: The platform should have the freedom to upgrade the Dapp whenever the developer wants. Also, if some bug does affect the Dapp, the devs should be able to fix the Dapp without affecting the platform.

Low Latency: Even with the lowest possible latency Dapp have to run as smoothly as possible.

Parallel Performance: In order to distribute the workload and save up time the platform should allow their Dapps to be processed parallel.

Sequential Performance: Multiple transactions cannot be executed in parallel it has to be done one at a time to avoid errors like double spends.

Smart Contract Auditing

An audit is a keen searching for a smart contract code for vulnerabilities, exploitative features, and inefficiencies to provide security against malicious actors and mistake. Audits are crucial to the progression of blockchain implementation and adoption. The new pair of skilled eyes required to view the code through the lens of an auditor is extremely important to secure against cryptocurrency loss, and/or data loss on behalf of the people that cannot. Auditors have to be even more cautious than project developers.

The smart contract audit can be either automatic or manual tests. Mostly automatic audit finds commonly encountered security vulnerabilities whereas manual test outlines efficient, logical, and optimization improvements. A smart contract audit is almost the same as a conventional code audit, it aims at finding security vulnerabilities before the deployment of code. The above-mentioned vulnerabilities like Over/Underflows, Reentrancy, and Front Running are most likely to be discovered using smart contract (Mishunin 2018) auditing.

Auditing Tools As Supplements

There are many software tools available on the market to aid in the auditing practice. Example, for detecting uint overflows and underflows a tool called Mythril can be used. Another tool is called Etherscrape, used to find reentrancy bugs when `send()` is being used. To bring together companies and freelance auditors when tools aren't enough, a decentralized auditing platform called Bountyone can be utilized. Note that, these tools can be employed as an additional security check, but it should not substitute the formal auditing process.

Formal Verification

Even though smart contract auditing provides a very fine layer of vulnerability detection, mathematical analysis, known as formal verification, helps to reduce instances of vulnerabilities further. Formal methods are the kind of mathematical technique used for the specification, development, and verification of both software and hardware systems. The process of accepting or rejecting the appropriateness of the proposed algorithms using a formal method is known as formal verification (Curran 2018).

A formal specification is used as the accurate output or result that a smart contract is expecting for, which a computer can check. After the contract compiled into the bytecode, the formal verification proves that the compiled bytecode implements the specification. However, manually performing formal verifications is a complicated process and at times comes with its own mistakes. And also verifying formal proof results can come with its variations.

Developer's Sharpness

Since blockchain's smart contract handles a huge sum of money, developers need to be very keen and do some sort of basic testing/verification from his side too. The first is a syntax topological analysis of the smart contract invocation relationship, to help developers to understand their code structure clearly; the second is a logical risk (which may lead to vulnerabilities) detection and location, and label results on the topology diagram.

Smart Contract Weakness Classification Registry

A comprehensive up-to-date list of known smart contract vulnerabilities and anti-patterns with real-life examples is found in the Smart Contract Weakness Classification Registry. Browsing the registry is an excellent way to keep updating with the latest attacks (consensys.github.io, Smart-contract-best-practices 2018). Link to the Smart contract weakness classification registry is given in the ADDITIONAL READINGS (smartcontractsecurity.github.io 2018) section.

FUTURE RELATED WORK

Though the above-mentioned solution helps to mitigate most of the common vulnerabilities, in order to ward off such attacks the auditing process should take an engineering approach, stringent verification with a background of theory and practice, as well as tool application. The standard software engineering framework is the need of the hour. The standardized approach helps the developers to code efficiently.

Blockchain-Oriented Software Engineering is needed to define new directions to permit effective software development. Modeling and verification frameworks, enhanced security, reliability, new professional roles, and specialized metrics are needed to take blockchain applications to the next trustworthy level. At least, the following three main areas are addressed as soon as possible.

- Best practices and development methodology
- Design patterns
- Testing

The aim of Blockchain-Oriented Software Engineering is to define new patterns, quality metrics, ad-hoc methodologies, fault analysis, security strategies and testing approaches capable of supporting a novel and disciplined area of software engineering. Still, need lots of research in the Smart Contracts security field (Destefanis, et al. 2018). Even after decades and the development of engineering approaches in traditional software development, the development of bug-free source code, is still a challenge. Error free code is even a more difficult task for blockchain software development, which started less than a decade ago. Vulnerabilities like the one leading to the Parity attack has clearly stated the need for adoption of the standard and best practices in Blockchain Software Engineering.

Testing the smart contract is challenging even critical because after deployment they become immutable, further testing or upgrading is not allowed. At present, smart contracts are not having a proper testing framework, meaning that every smart contract needs to be tested manually. Because of the criticality of the application and disability to update once deployed nature introduces much more complications to test. Hence, it is desirable to utilize, robust testing techniques. Even though manual testing is likely to form an essential component, but is certainly limited; there is a need for effective automated test generation (and execution) techniques.

CONCLUSION

In real business scenarios, especially ones with a complex business model for smart contracts still have a long way to go. As blockchain technology is still an emerging field, there is no go-to resource for all-encompassing solutions. There is also a need to discover a way to update smart contracts to take into account of evolutions, that is, we need a strategy that can be exploited for debugging purposes, refactoring, the new features, and, in general, for purposes similar to the version in traditional software engineering. In the future, smart contracts will need to be much more robust, not only in function but also in flexibility and security, to satisfy multiple business scenario. Nevertheless, as of now, the smart contract security lies in the hands of every stakeholder.

KEY TERMS AND DEFINITIONS

Auditing: The process of conducting an official inspection of a company or its accounts.

Blockchain: A digital ledger in which transactions made in cryptocurrency are recorded chronologically and publicly.

Cryptocurrency: A digital currency in which encryption techniques are used to regulate the generation of units of currency and verify the transfer of funds, operating independently of a central bank.

DAO: Is an organization represented by rules encoded as a computer program that is transparent, controlled by shareholders and not influenced by a central government.

Dapps: Decentralized applications (dApps) are applications that run on a P2P network of computers rather than a single computer.

Ethereum: Is an open software platform based on blockchain technology that enables developers to build and deploy decentralized applications.

Smart Contract: Is a computer code running on top of a blockchain containing a set of rules under which the parties to that smart contract agree to interact with each other.

The Challenges and Future of E-Wallet

Chiam Chooi Chea

 <https://orcid.org/0000-0002-7403-0320>

Open University Malaysia, Malaysia

INTRODUCTION: BACKGROUND

The term “cashless” is heard on a daily basis these days and it is called digital payment with no cold, hard cash involved. The transactions are made via electronic transfers where it only takes a tap of a smartphone or scan of a QR code to complete the process. E-wallet is an electronic device or an online service that enables electronic transactions. This includes purchasing items online, where banking accounts, bank cards, IDs etc can be linked to the digital wallet. Payments or purchases can be made with just a click away, with those banking and personal information stored in the system. E-wallet is surfing on the e-payment world currently and seems to stay for a long time. A note to consider is that digital wallets are not all about making transactions, but also to authenticate the purchasers’ credentials, such as; e-wallet could verify the age of the buyer to the store while purchasing alcohol or cigarettes. E-wallet proposes easy and safe transaction for purchasers as consumers are not required to fill out particulars when they purchase because the information has already been stored or saved in the e-wallet system. Other than that, due to rising number of snatch theft or crimes worldwide, e-wallet is a cashless transaction, hence the safe feature being embossed in it. On the other hand, e-wallets are made available to consumers without any charges.

The term e-wallet, mobile wallet, electronic wallets, virtual wallets, digital wallets, cashless transactions, mobile payments and similar terms are used interchangeably among consumers and sellers. These terms are mobile applications that enable financial transactions. Although e-wallet concept more pros than cons, it may not seem that many people are using e-wallet technology at the moment. Few years ago, most of the players in the banking industry foresee that e-wallets would take over the usage of cash and credit/debit cards (plastics) by consumers quickly. However, e-wallets haven’t exactly taken off and consumers’ reception and interest do not seem to take off and this shows that the concept of e-wallets still have a long way to go. What can be reasons for this phenomenon? Most of the prominent shops, whether it is online or walk-in are introducing the e-wallet concept for its buyers. The question remains, is this the future way of making payment when purchasing online or walk-in? Is the e-wallet function the same as our physical wallet in our actual wallet? Is there only one e-wallet for all the shops and purchases? At this moment, there are many different e-wallets platforms for different shops and each time the purchaser need to top-up or reload money in the e-wallets, it seems to pose as a hassle more than convenience and it is merely almost impossible to really empty the e-wallet to zero amount. There will be somehow some cents or dollars in these e-wallets. The e-wallet is in the current wave for the younger purchasers due to its “cashless” and “pay anytime” concepts. There are many perspectives that need to be considered before e-wallet makes it mark in the market entirely, such as; older generations reception, problems to eye-sight due to age, the e-wallet platform readiness, law pertaining to e-wallet, safety features of e-wallet, new trend of cyber crime arises, internet accessibility, stability and its speed in the country etc all make e-wallet little tougher on rising on a full scale. Other than that, consumers do

DOI: 10.4018/978-1-5225-9715-5.ch063

not seem to like to go through the hassle to change that provide little differences between plastics and e-wallet. Both are cashless and, plastics are somehow very convenient too, just swap and sign or swap with 6-digit pin number at the counter. E-wallets need to have more benefits or perks than plastics in order to win over these plastics consumers. Currently, credit cards are the most popular mode of payment for consumers in the world followed closely with debit cards. Nevertheless; it is difficult to know the future given the stealth ability of e-wallet tools.

FOCUS OF THE ARTICLE: E-WALLET KEY TAKEAWAYS

CMB Consumer Pulse (2015), highlighted several key takeaways for E-Wallet:

- 2015 is the year when mobile payments take off and rewards and discounts won't be the only motivators—Familiarity and usage have doubled since 2013; with 15% having used a mobile wallet in the past 6 months and an additional 22% likely to adopt in the coming 6 months. Rewards and discounts are compelling to potential users but alternate uses including the ability to use a device as a photo ID or in spend management are also compelling.
- Barriers to mobile wallet adoption are diminishing overall—Security concerns remain the number one barrier to mobile wallet adoption—however just 62% of respondents list security as the number one barrier, down from 73% in 2013. The near ubiquity of online shopping (86% have made a purchase from their desktop or laptop in the past 6 months) may be acclimating consumers to perceived security risks like identity theft.
- Wearable technology, often called “wearables,” is clothing or accessories that incorporate computer and advanced electronic technologies. The designs often incorporate practical functions and features, such as pedometers, heart rate monitors and activity trackers. Wearables set to pave the way for mobile wallet adoption. While many consumers don't yet see the benefit to using their phone at the point of sale, the ability to scan a wearable device, like a smartwatch, at the register may help customers overcome this convenience barrier. Nearly 40% of those highly likely to buy wearables in the coming year want it to come with mobile wallet functionality. And the majority of likely wearable buyers claim that the presence/absence of a mobile wallet has a major impact on their purchase decision

E-WALLET FEATURES

E-wallet is known as digital wallet is an electronic device or an online service that enables electronic transactions. E-wallets companies have been ramping up on their infrastructure with several features to capture the interest of consumers. The following are some of the common features of e-wallet:

- Payments are made immediately- Customers can make cashless transactions without much hassle.
- E-wallet apps are free of charge and can be installed rather easy stored with personal and banking details.
- Able to transfer and link to bank accounts and able to make payments via these accounts and e-wallet app.
- Accumulate points and redeem points for cash vouchers or other benefits such as additional offers and discounts vouchers
- Split bill- Several e-wallets apps allow the customers to split the expenses with the same wallet users. Doing this will generate a payment link with banks accounts
- Chat messenger integration- E wallets has integrated its payment service through chat messenger in order to increase your convenience further

Many technology supporters indeed realise the fact that demonitisation is here to stay and the convenience of e-wallets cannot be possibly ignored, hence consumers should take it upon themselves to use cashless transaction methods such as e-wallets to the fullest. Nevertheless, there are many setbacks for e-wallet and it has reached its fullest potential. E-wallets able customers to send payments for things purchased with just a few taps on the mobile phones or laptops. Customers have to follow several steps to complete the transactions and the payment will be deducted from the customers' e-wallet and the amount will be credited into the merchant's e-wallet account. It is similar to face-to-face transactions except it is all done without any physical cash in play. E-wallets have several advantages over physical cash. Digital money is safer to carry around, especially if you need to make large payments. Other than that, it keeps records of all the purchasers' transactions and its amounts, which enables the purchasers to manage their finances in better manner.

TYPES OF E-WALLETS AND ITS PERKS

There are many mobile wallets options to one can choose from and it all matters on individual preference as well as the perks and benefits they offer to its users. Although, there are users who will remain with their bank's app, but many would try out other mobile wallets which offer better features that banks could not match technologically. Some examples of e-wallets which are supported by most mobile devices:

E-Payments Services

It refers to services provided by e-commerce payment systems in online purchases. Mobile apps created by banks is under this category, however the most popular mobile wallets with e-payments services tend to be developed by tech giants. Google Wallet, Apple Pay, Samsung Pay, PayPal which offer comfort to users due to their solid reputation.

Loyalty and Coupon-Based Wallets

Customers these days are very alert and wary on loyalty benefits, coupons-based mobile wallets. Apps such as Gyft, Key Ring and LevelUp are making its way to the customers' choice list due to its perks and benefits. The Starbucks mobile wallet is a favourite among many of its enthusiasts, and offers app-only promotions. These apps can link and store all of your loyalty card accounts under one account and cus-

tomers are still able to use these loyalty cards to collect reward points or bonuses. It provides convenience to customers as they do not have to carry all the cards around when doing their shopping.

Peer-to-Peer Payment Wallets

Mobile wallets such as SquareCash, Venmo and Circle are categorised under peer-to-peer payments between friends and family. It's designed to provide convenience for paying back the money one owes to his/her acquaintances. It is able to eliminate the awkwardness when asking people who owe one's money to pay back.

Cryptocurrency Wallets

Many cryptocurrencies are still not at their mature stage. Bitcoin is the most mature cryptocurrency to date and Bitcoin wallets work like regular wallets, except that instead of USD, the purchaser sends the Bitcoin-value equivalent at the time of payment instead. The merchant will provide a Bitcoin address (alphanumeric code or QR code) that the purchaser can enter as the destination address. The value of Bitcoin changes often, so you might want to time your purchases.

Hybrid Wallets

A hybrid wallet is a form of mobile wallet that supports both digital currencies and traditional cash currencies in the same platform. Wirex is an example of a FinTech service which. It's like a combination of a banking account with Bitcoin wallets. The purchaser's account can have both cash and digital currencies, hence, it's an interesting product as it provides alternatives and options for purchasers and it can be appealing to as each alternative has its benefits one can benefit.

Remittance Wallets

Remittance wallet is similar to peer-to-peer payment wallets, with an additional focus and emphasis on the receiver (who tend to stay in developing or third world countries, where literacy might be an issue) to collect the money. International remittance is a big market. Wallets such as Remitly and Xoom are marketed with this in mind. It is a helpful money-saving tool for people who send money to countries where much of the population are bankless.

Messaging App Wallets

Messaging app wallets are still relatively new. For example WeChat can only be used in some stores in China, and Facebook Messenger just integrated PayPal payments. WeChat, Telegram and Facebook Messenger can all be used to receive money from third party to pay for the products and services.

Figure 1. Consumers' preferred method of payment

Source: Mintel, 2018

CONSUMERS' PREFERRED METHOD OF PAYMENT

In a study by Thrive Analytics (2018), socio economic demographics were the key factors in capturing “new consumers” for e-wallet services. Refer to Figure 1 and Figure 2 for the details on consumers' preferred method of payment as well as consumers who do not want to change their payment methods. Key findings from Mintel (2018), the survey indicated that consumers do carry lesser cash today, especially females, with 50 percent of all consumers carrying less than \$20 on a regular basis. From the survey results, three out of four are under the age of 40 do not carry any cash at all. Other than that, approximately 60 percent of all digital wallet users are male despite carrying more cash than females. Females (18-29 years old) tend to use merchant digital wallet apps more often than males to look for discounts/ coupons, with 72 percent and price shop, 56 percent. Meanwhile, males tend to browse and engage in service related activities such as paying bills and browsing through retailers' product and contact information when they use merchant apps. The most digital wallet usage was done through mobile phones with approximately 60 percent for purchases under \$10; with entails daily products such as groceries, retail items, games and books.

WORLDWIDE MOBILE PAYMENT PLATFORMS IN 2017

The highest number of users in the mobile payment platform is Wechat pay, which is widely and popularly used in China due to the fact that China is rising as a one of the leading countries in the world. This may be due to the fact that, it has since practiced open economy with the introduction of its “one belt one road” concept to the world, besides of being one the most populated countries in the world. China is one of the largest markets in the world and this makes China is a strong spending power due to

Figure 2. Consumers who do not want to change their payment methods

Source: Mintel, 2018

Figure 3. Statistic reports on the number of users of selected mobile payment platforms as of August 2017

Source: The Statistical Portal, 2017

its high number of consumers from the country. Refer to Figure 3 for the statistic reports the number of users of selected mobile payment platforms as of August 2017. According to the findings, 600 million users had been reported to have used WeChat Pay as their mobile payment platform. Alipay was ranked second with 400 million users worldwide.

Challenges of E-Wallets

According to Vulcan Post (2017), there are many challenges and obstacles that e-wallet faced and the expected reception for e-wallet is not as good as expected due to several seen and unforeseen factors:

Setting Up Can Be Hassle

Although the e-wallet concept promises easy and seamless transaction, nevertheless the start-up may not be as easy as one thinks and can pose as a hassle for the users even more if one have never used cashless before and are not sure what to do. There might be a need to give banks a call to enable e-commerce transactions and the fact that some additional efforts are needed can deter users.

Lack of Trust on E-Wallet

According The Financial Brand (2018), consumers may like the idea of a cashless society, but they still have serious reservations about mobile wallets due to many reasons, with security issues topping the chart. Approximately 43% of consumers don't think mobile wallets are secure, and 38% are concerned about losing their device and therefore being unable to make any payments. In the same study, it was found that more than half (55%) of consumers prefer to use credit cards due to safety concerns.

It Is Not Entirely Free

Although a wallet is free for consumers, vendors charge merchants for wallets. Some wallet vendors make arrangements for merchants to pay them a percentage of every successful purchase directed through their wallets. In other cases, digital wallet vendors process the transactions between cardholders and participating merchants and charge merchants a flat fee and that fee are usually transferred to the consumers.

Security Features Issues

Although retailers and merchants tout the best cashless system with its best security protection software and firewalls, there is no guarantee that the system will work smoothly without any flaws. There is a saying "there is never a guarantee with anything that deals with technical issues". Although all are in order, the system can be down or crashed in just a few seconds. No system can guarantee with 100% assurance that data wouldn't be stolen, and money siphoned off. Many were taken aback with technology when there is hack or "taken hostage" in the laptop or personal computer itself. Eg. The ransomware WannaCry that managed to shut down entire companies from operating due to a small flaw in the Windows systems they were running.

Fear of Cyber Attacks

Due to revolution and the rage wave of cashless, hackers are getting bolder and better at cracking the security firewall of these security firewalls and security systems for cashless. Regardless of how well the retailers and owners of these cashless systems tout the best protection of these security software and firewalls, there will be no 100 percent guarantee with 100 assurance that the data will not be stolen or hacked or taken "hostage". One of the cyber attacks that make its way to the headlines lately is a ransomware "WannaCry" that is able to take "hostage" and threatened to shut down entire companies from operating due to a small flaw in the Windows systems they were running.

Not Enough Shops Adopting Cashless, or Implementing It Well

Although the cashless payment terminals are going viral but at times the terminal is not really functioning or the system is down at the store. This poses a real nuisance, and instils disappointment, dissatisfaction and distrust in customers. This has happened in various shops from fast food restaurants to prominent retailers. Often, it's not that they don't have terminals in place. This may be due to inadequate onboarding, lack of proper staff training, difficulties in migrating some functionality, to streamlining the process to work their established tallying systems, some existing companies might still find it easier to only take cash as a means of purchasing. A note worth noting is due to user demand as well. The vendors could have set up the terminals, but if not many Malaysians are actually using cashless, then merchants really have no reason to leave the option enabled.

Accessibility for All

Smartphones are no longer luxury items as it became a necessity to most people as the penetration of smartphones is quite high and it is expected to be growing exponentially. However, there are some minorities who do not own and coping well without a smartphone. Are we leaving and side-lining these people behind? There are people who do not own a smartphone with various reasons- illiterate, financial issues and un-tech savvy etc due to old age, education and financial background? The obvious losers would be those of the aging population who are slower to absorb information about new technologies, at their age or even younger people who might not have bank accounts yet. Then, there are also those who are of a lower income, who often get paid purely in cash. People who are unbanked or who don't have enough money to start a bank account are automatically discriminated against when a society goes cashless. On the other hand, lower income people will not be able to afford to own a high-end mobile phones, with system that support these apps. It would be an additional burden for this category of people. Is it really fair to impose these technologies which they do not need or do not to embrace on their shoulders? Is it fair to say "We need to keep abreast with changes in order to stay ahead and those who do will be left behind" for every case as being treated fairly is what the world is trying to reach today.

Cashless may be the new upcoming trend in the future, due to its convenience but there seems to be many issues starting from technicality to consumers' need to be addressed before the "cashless" can take over from the plastics as it does not seem to be a need and it is not necessary to go totally cashless in transactions. Although many countries do not have much need to adopt this system, but many are trying to go down this path in order to keep up to date with the current technological trends. A study was conducted in United States at 2017 on the reasons why consumers are not using e-wallet. Figure 4 illustrates the statistic on barriers to digital wallet adoption according to consumers in the United States as of November 2017. During the survey period, it was found that 39 percent of non-mobile wallet using respondents were hesitant to use digital wallets due to security concerns (The Statistical Portal, 2017).

CRIMES RELATED TO E-WALLETS

As stated earlier, one of the most concerns of e-wallet is its security. Due to cashless world and concept, there has been a new and on-going evolution of crimes pertaining to online payment for the cashless society. A new technique has surfaced in which hackers and fraudsters are siphoning money through people's e-wallets using phishing techniques. A hacker can trick a user into downloading a modified or

Figure 4. The statistic on barriers to digital wallet adoption according to consumers in the United States as of November 2017

Source: The Statistical Portal, 2017

a disguised version of the e-wallet applications by offering free credits and money which could be hiding hard-to-detect computer viruses like a Trojan. Besides losing the money in the e-wallet, users are very concerned about exposing personal information which can be obtained when registering for the e-wallet and even giving the hackers full access of your phone remotely. Mobile phones are considered a must-have item and a treasure full with personal passwords, personal notes as well as credit card and log-on details and the stakes are growing exponentially as the time goes. The growing and tempting stakes cause the continuous growth of cybercrimes around the world.

THE ANNUAL PAYMENT TRANSACTION USING E-WALLET

The annual payment transactions in US billion dollars from year 2015 to year 2021. The data for year 2018-2021 are projected. Figure 5 gives information on the proximity mobile payment transaction value in the United States from 2015 to 2021, in billion U.S. dollars. In 2021, near-field-communications or other contactless technologies are projected to generate close to 190 billion U.S. dollars in transaction value. As of 2015, about 12.7 percent of smartphone users in the United States were actively using proximity mobile payment services. Industry experts project mobile proximity payments to be amongst the most successful future mobile payment methods. Popular application areas are paying for transport and transit, as well as retail goods and services. According to a survey of digital payment users, the most common mobile in-store mobile payment method was barcode or QR code scanning and a further 12 percent had waved or tapped their mobile phone to pay at check out. Mobile wallet apps are used to facilitate mobile payments. PayPal, Google Wallet and Apple Pay are amongst the most popular digital wallet services according to users in the United States. A current example of mobile proximity payment usage is Starbucks. The coffee retailer allows customers to pay via mobile app by waving their phone at the checkout counter. Starbucks processes more than 8 million weekly mobile app payments, which account for 16 percent of all transactions.

Figure 5. The statistics on barriers to digital wallet adoption according to consumers in the United States as of November 2017

Source: The Statistical Portal, 2017

Figure 6: Digital payment methods by North American retailers as of December 2017

Source: The Statistical Portal, 2017

THE INTENTION TO ACCEPT THE DIGITAL PAYMENT METHODS BY RETAILERS

Based on a study in North America as of December 2017, we can see that 37 percent of responding North American retailers was already accepting customer payments via PayPal with 14 percent planning on accepting the payment method within the next 12 months. Figure 6 presents the most common digital payment methods that North American retailers accept or plan to accept. Mobile payments have become increasingly main stream in the United States as an increasing number of users take advantage of the conveniences of digital payment options. Scanning barcodes or using mobile apps are the most popular mobile payment methods among U.S. users. More than 12 percent of mobile payment users have purchased goods at a store using their mobile device. Mobile proximity payments enabled through near-field-communications (NFC) are also projected to vastly increase to 118 billion U.S. dollars in

2018, up from 3.5 billion U.S. dollars in 2014. According to industry professionals, mobile proximity payments are one of the mobile payment types most likely to succeed. According to smartphone users in the United States, mobile payments are a convenient way to pay for many reasons. Some of the benefits of mobile payments include the speed of payment, the convenience as well as the integration with pre-existing loyalty and coupon programs. Another well-received advantage of mobile payments was the ability to pay without sharing financial data with retailers.

THE FUTURE OF E-WALLETS

Due to its many setbacks and challenges of e-wallets, the future for mobile wallets is hazy at this point, although it seems hard to believe that in an increasingly wired world that more and more payments might migrate to digital channels. The peer-to-peer payment platforms like Venmo and Zelle have been well-received by consumers, however inertia is a powerful force, and change doesn't come easy. Change would not be easy unless it proves a total new breakthrough from the current practice. While digital payments are steadily growing in popularity, cash remains very much a part of consumers' financial lives, even in the least cash-friendly countries, perhaps due to the fact that physical cash provides a "sense of security" that virtual cash could not. With the rise of "cashless" world, it seems to have the tendency to sideline the minorities' purchasers such as the illiterate and financially poor purchasers.

Some users would perceive that mobile wallets would not be a widespread adoption phenomenon since it does not seem to solve the consumer problem and consumers may not want to make it as a habit to use e-wallets. Therefore, the road for e-wallets would not be an easy one. Nevertheless, consumers can be convinced rather easily when it involves monetary benefits. Loyalty programs will be a significant driver in retailer mobile wallet adoption.

SOLUTIONS AND RECOMMENDATIONS

E-wallets have great potential to take over the transactions world if the setbacks and challenges are mitigated. There are still worries and doubts by many consumers by the term "virtual payment". The most common reasons why consumers are reluctant to adopt mobile payments are:

- It's not available at stores
- I would want to use it
- Technology doesn't always work properly
- I don't know which app is the best
- Credit cards have better rewards
- No single payment system across merchants
- Not as convenient as using cash or a credit card
- I don't want the store to have my mobile wallet info.
- I don't want to pay any fees
- I am worried about security
- The mobile screen is too small to make transactions

Source: CMB Consumer Pulse (2015)

Figure 7. The methods to increase adoption of mobile wallets as of June 2018
Source: Mintel, 2018

SOLUTIONS FOR CONSUMERS' CONCERNS ON E-WALLET CRIMES

- Fear of losing personal information from smartphone theft is the main fear for users. Enhancing the security software and ensure contingencies and refunding the money to purchasers' mechanism with convenience is in place. Priority should be given to the purchasers in order to gain their trust and also provide a sense of security to them.
- Integrate the same categorized payment platforms under one roof instead of several different apps which can be a nuisance to consumers
- Provide alternative payments for various consumers especially those who are illiterate, not tech-savvy consumers
- Ensure the payment terminal is in place and adequate trainings are provided as it can provide an assurance to the users.
- Easy account set-up for first-time users as this can hinders many potential users to walk-away from mobile wallet and tend to look back to physical cash payment.
- Provide more types monetary benefits to users. According to a study by Mintel (2018), it presents a significant opportunity for financial marketers looking to increase adoption of mobile wallets where discounts, rewards and coupons could get consumers to switch their payment type over to mobile wallets. Refer to Figure 7 for the methods to increase adoption of mobile wallets.

CONCLUSION

Consumers have split views on the future of cashless society. Some think that payments will become completely cashless within their lifetime as digitalization of payments can be considered as a boon to growth of a country's economy, while some do not share the same view as half of those believe that cash will disappear within the next five years. There can be more concentrated effort to bring users on board with mobile payments. E-wallets is a double-edge sword as on one hand, it provides the convenience to its users as it records all the payments from the amount, products and place and everything and it enables the consumers to track its expenses and manage his/her finance better. However, on the other hand, it is also a worry to users as it records everything about his/her spending patterns, favourite

place to dine, shop etc. All this information can be lethal to users if it falls into the wrong hands. The mobile wallet market is still evolving with no clear competitors claiming a definitive win. However, familiarity and comfort with online payments have translated to high awareness and satisfaction for a number of providers. According to Bluefin (2017), the mobile wallet marketplace remains fragmented and customers remain loyal to traditional forms of payment, mobile loyalty cards will lead the way toward a consumer landscape driven by mobile wallets. By 2020, transactions made using mobile wallets will reach \$503 billion.

FUTURE RESEARCH

A lot of security aspects are still left unexplored in this context. Information technology has to work hard towards making the transactions secure and complete as this is one of the major hindrance in the success of digital payments. One worthy note is that the possibilities of all the e-wallet providers to have a unanimous perspective how e-wallets can be implemented with a tighter and stronger security features. Other than that, the possibilities of mobile wallets could be introduced in transportation services in busses as a lot of cash transaction is involved on daily basis can be further explored. There is a need to address the gaps that exist between what customers want and what are being offered to them by merchants.

INTRODUCTION

In this technological age, there exist different innovative money payment systems through which financial transactions are made possible and many of these money payment systems are built to run on platforms such as the Web and smartphones (Nian, Lee, & Chuen, 2015). These money payment gateways have enjoyed a continued growth, from the likes of SlydePay, ZeePay, Skrill, BitPesa, Apple Pay, Google Wallet, M-Pesa, BitPay and PayPal (Nian et al., 2015). In ensuring secured transactions on these platforms, the phenomenon of cryptocurrency is emerging. According to Nakamoto (2008), transactions on the web has come to depend exclusively on Financial organizations filling in as trusted third parties to process electronic installments. In spite of the fact that these frameworks work well for most electronic exchanges, it keeps on suffering from the genetic shortcomings of the trust-based model which are also known as “third-party based” payment processing systems. Contracts entered by trading parties are not enforced by these “trust-based” or “third-party-based” payment processing systems (Master Card, PayPal, American Express, SlydePay, and so on). Since contracts entered are not enforced by these trusted third-party payment processor, additional costs are being incurred by trading parties in their quest to ensure that the trade executed is based on the terms of the contract (Knott, 2013).

A Cryptocurrency is a digital or virtual currency that uses cryptography which changes data into a mystery code for transmission over an open system for security and was the first truly decentralized and digitized modern money (Nakamoto, 2008). With the use of special cryptographic techniques, signatures and also an incredible rewarding system, one can say that cryptocurrency is unlike any currency in the world. It requires no third parties such as the banks, credit card companies and others, just a peer-to-peer transaction which means from the sender directly to the receiver (Lee, 2013). Bitcoin is one of the cryptocurrencies in the world. It first appeared online in January 2009. The creator was a computer programmer under the name Satoshi Nakamoto. His open source invention was peer-to-peer which meant transactions did not require an intermediary like Skrill or PayPal to function but rather be electronic with absolutely no physical involvement. Unlike traditional money, Bitcoins exist only online, and they are

DOI: 10.4018/978-1-5225-9715-5.ch064

not considered as legal tender. Also, Bitcoins are not backed by any government or any legal entity, and their flow is not controlled by a central bank. With no third parties involved in transactions, the Bitcoin system is a very private one (Elwell, Murphy & Seitzinger, 2013).

This new mode of online financial transactions with bitcoins has transformed the perception of money in the form of traditional money as paper, coins, cheques, treasury bills, and so on, into seeing it in the form of mathematical money as digital ones and zeros or bits (Antonopoulos, 2015). In April 2016, the highest interest shown by African countries in bitcoins was Ghana. Ghana was ranked at number one with 100% interest in Africa (Scott, 2016). The creators of Dogecoin (a cryptocurrency) donated \$342 USD to the Ghana Medical Help (2016) to purchase medical equipment. They also created a Cryptocurrency Endowment Fund to accept donations from donors using cryptocurrencies (Ghana Medical Help, 2016).

Kubát (2015), hailing the innovativeness of Bitcoin, revealed that, judging from the opinions of the respondents, majority considered Bitcoin as a positive mode of transaction. They were optimistic that Bitcoin would represent a decentralized and a virtual new currency that would be out of the control of any governmental agency. Bitcoin is therefore a cheaper way to spend money even across national borders. Majority of e-commerce sites accept Bitcoins. In addition, many Bitcoin ATMs have been opened and one can even pay for college tuition fees with it. Bitcoin is like gold, but in a virtual environment (Rogojanu & Badea, 2014).

Bitcoin offers a secured mode of transaction. For instance, only owners of Bitcoin wallets can change their Bitcoin address. No hacker can illegally get access to Bitcoins unless they have direct access to the user's computer. Again, the Bitcoin system requires physical access unlike traditional currency where only a few verification steps are required to gain access to the account, which makes it almost impossible to hack (Dwyer, 2015).

With the fast growth of Bitcoin transactions, initial literature reviewed espoused that Bitcoin usage and its activities have gained considerable traction in developed countries and also that it is gaining grounds in some developing countries in Africa, Ghana included (Scott, 2016). The proposed research will therefore attempt to explore the adoption and usage of the Bitcoin technology among citizens of a developing country such as Ghana.

Over the years, users of fund transfer services and payment services have had to contend with unfavourable circumstances in the hands of middlemen (such as bank, a credit card company, and the telecommunications companies (Telco's) via m-payment systems) who hide behind these virtual services during business transactions. Sending funds to another person attracts high transactional fees and the total amount sent to the receiver is decreased on arrival (Dwyer, 2015). Elwell et al. (2013) concluded that Bitcoin transactions are to be significantly less expensive for users as compared to other traditional payment systems. Banks and Credit card companies for instance will charge merchants significant fees for their role as a trusted third-party intermediary in validation of an electronic transaction. Again, Njuguna (2014) found out that BitPesa is one of Africa's first Bitcoin startup that is making transfer of money from Kenyans living in UK to their loved ones in Kenya more efficient and possible. Extant studies (Kubat, 2015; Bonneau et al., 2015; Elwell et al., 2013; Dwyer, 2015; Singhal & Rafiuddin, 2014) have also looked at how cryptocurrencies have digitized and decentralized the modern currency system. Again, studies (Nakamoto, 2008; Nian et al., 2015; Njuguna, 2014) have looked at how Bitcoins are made and used, how beneficial it is to its users, and how its adoption has helped eased transactions locally and internationally? However, while there is a significant amount of evidence that Bitcoin actually cuts down on the cost of funds transfer across the world, arguably, there exists little or no comprehensive data on its existence, adoption, usage and its cost advantage from a developing country perspective.

The proposed research is exploratory since Bitcoin in the Ghanaian community is at its duding stage and is gradually gaining recognition in the Ghanaian marketplace. Many people in the country do not know what this great innovation is (Njuguna, 2014). As a result of the challenges in the adoption of Bitcoin, relevant guidance is needed to help individuals tap into the massive benefits of using Bitcoin. The usage of m-payment services in the country have skyrocketed. This means that there is need for researchers to explore challenges in the adoption of cryptocurrencies in the country.

The purpose of this study is to explore the determinants of Bitcoin adoption in Ghana and to assess the nature of the usage of the Bitcoin technology payment preferences in transactions.

The following outlined objectives will be achieved by the research:

1. To explore the nature of Bitcoin adoption in Ghana
2. To explore the determinants of bitcoin adoption as a payment option in Ghana

The following are the research questions asked:

1. What is the nature of Bitcoin adoption in Ghana?
2. What are the determinants of Bitcoin adoption as a payment option in Ghana?

The significance of this study can be investigated along research, policy, and practice. It will be critical to help contribute to the current learning bank of Bitcoin literature.

This study is to explore the determinants of Bitcoin adoption in Ghana and to assess the nature of the usage of the Bitcoin technology payment preferences in transactions. The Chapter is organized into five sections. The first section is the introduction to the chapter. The second section presents an overview Bitcoin and the Blockchain, advantages and disadvantages of Bitcoin, related work on Bitcoin and the research framework as well as the research methods used in the chapter. The third section deals with the data presentation, analysis of findings and discussion. The fourth section presents future studies directions. The last section deals with precis of the studies, implications (and suggestions) to investigate, practice and policy.

BACKGROUND

Bitcoin and the Blockchain: An Overview

Cryptocurrency was initially introduced at a time of economic instability (Ross, 2015). Over the years, Bitcoin, has been one of the interesting phenomena in the world (Kubát, 2015). Bitcoin was created with the aim of simplifying and solving transactional problems online.

Bitcoin is a decentralized payment scheme that facilitates peer-to-peer transactions between users; it allows user “A” to transact with user “B” directly without any third party involved (Thukral, 2017; Nakamoto, 2008) without depending on shared trust. The Bitcoin system has no incorporated issuing party. The information of every one of these exchanges, in the wake of being approved with a proof-of-work system, is gathered into what is known as the Blockchain. The system is customized to expand the cash supply in a gradually expanding geometric arrangement until the point when the aggregate number of Bitcoins achieves a furthest utmost of around 21 million BTC’s (Nakamoto, 2008).

Table 1. Sample related studies on bitcoin adoption

Article	Theory	Country	Sampling & Method	Adoption Determinants
Ermakova et al. (2017)	Diffusion of Innovations	Germany, Austria, Switzerland, UK, USA and Israel	Mixed Methods: empirical survey of around one hundred Bitcoin Experts	Anonymity and security Absences of central point of trust Theft or loss of Bitcoins Unpredictability and insecurity of the Bitcoin system
Folkinshteyn & Lennon (2017)	TAM	USA	Qualitative: a detail-rich in-depth single case developed from direct interviews conducted by the authors with the founder of blockchain startup Bidbit.	Perceived ease of use Perceived Usefulness Perceived risk
Zarifis et al. (2015)	Digital Currency Trust Model	Europe and North America	Quantitative: 562 Online Buyers	Trust
Njuguna (2014)	Diffusion of Innovations	Kenya	Qualitative: case study	Lower transaction costs Increased privacy Long term protection of loss of purchasing power from inflation

The Blockchain aids the Bitcoin framework to maintain a worldwide, freely conveyed record of exchanges, which is kept up through an algorithm running over a substantial number of Personal Computers appropriated over the world. These PCs play out a computationally intricate task called mining, which incorporates the exchange into the Blockchain. The transaction to charge from the sender's record and credit to the receiver's record is totaled with other pending transactions together into a block by one of these machines and presented on the top of the Blockchain (Nakamoto, 2008).

Advantages and Disadvantages of Bitcoin

Bitcoin has a number of advantages and disadvantages that will influence its adoption. The advantages are: No inflation due to political forces, Peer-to-peer cryptocurrency network - where transactions are without no third parties, no boundaries - which makes it possible to send transactions across countries, low transactional costs, Anonymity, transparency, etc. (Ivaschenko, 2016). The disadvantages of Bitcoin coin are that, it is highly volatile, can encourage money laundry and used for other illegal activities like funding of terrorist groups and the purchases of illicit drugs (Ivaschenko, 2016).

Related Work on Bitcoin

Extant studies have explored Bitcoin adoption from various perspectives, although all at the individual level but in different geographic contexts. This includes Ermakova, Fabian, Baumann, Izmailov & Krasnova (2017) in Europe/North America (Germany, Austria, Switzerland, UK, Israel and USA); Folkinshteyn & Lennon (2017) in USA; Zarifis, Cheng, Dimitriou & Efthymiou (2015) in Europe and North America; and Njuguna (2014) in Kenya as shown in Table 1.

In addition, Bitcoin adoption has also been studied using various theories such as TAM, DOI, and Digital Currency Trust Model. Yet, results from these studies have been inconclusive. Arguably, in the case of developing economies, little literature about Bitcoin adoption exist, thus there is the need for more studies in developing countries context in order to understand this phenomenon. In relation to Table

1, adoption determinants in developing economies differ from the developed economies. For instance, whilst studies from the developed world looked at Anonymity and security, Absences of central point of trust, Theft or loss of Bitcoins, Unpredictability and insecurity of the Bitcoin system, Perceived ease of use and Perceived Usefulness, Perceived risk and Trust (Ermakova et al., 2017; Folkinshteyn et al., 2017; Zarifis et al., 2015), a study from a developing country context suggested lower transaction costs, increased privacy and long term protection of loss of purchasing power from inflation to be the main factors to the adoption of Bitcoin (Njuguna, 2014).

Again, from Table 1, most studies were conducted in Europe and North America, which are developed economies, whilst few have been conducted in developing countries. Therefore, this study employs a theoretical approach to investigate Bitcoin adoption from a developing economy's perspective by adapting the UTAUT 2 model.

RESEARCH FRAMEWORK

The UTAUT2 Model

The aim of this study was to examine the factors affecting Ghanaians' intention to adopt and use Bitcoin in their transactions. These indicators that may affect the adoption of the technology are illustrated in Figure 1.

The improvement of the Unified Theory of Acceptance and Use of Technology 2 model (UTAUT2) had its hypothetical establishment on the UTAUT model by including three (3) extra additions, to be specific, price value, habit, and hedonic motivation (Venkatesh, Thong & Xu, 2012).

UTAUT2 and huge numbers of its forerunners were for the most part used to gauge the selection of data innovation frameworks (which examines info systems adoption). It includes the accompanying builds such as: Effort Expectancy, Performance Expectancy, Social Influence, Facilitating Conditions, Habit, and Hedonic Motivation (Roos, 2015).

Research Propositions

Performance Expectancy: This shows how much an individual assumes a technology or a system will be effective in the accomplishment of progresses in work execution (Venkatesh et al., 2012). It is the expectation of Ghanaians that Bitcoin will aid in the quick and successful completion of transactions. This will then make them have an intention to adopt Bitcoin. Zhou et al. (2010) found that performance expectancy has significant effects on user adoption of a technology. In another study, Chang, Yan & Tseng (2012) also found a significant effect of task technology fit on performance expectancy. Therefore, the researchers postulate that:

P1: Performance expectancy has a generally solid consolation on an individual behavioral aim in utilizing Bitcoin.

Figure 1. Bitcoin adoption framework

Effort Expectancy: This echoes the client's impression of the fact that it is so hard to utilize the innovation (Venkatesh et al., 2012). Ghanaians expect the use of Bitcoin to be smooth, easy and intuitive. They expect the utilization of Bitcoin to be user friendly. Effort expectancy is a significant predictor of the intention to adopt a technology (Deng, Liu & Qi, 2011). Also, Effort expectancy impacts the overall use of intention of a technology (Helena, Fang & Tseng, 2010). Therefore, the researchers postulate that:

P2: Effort expectancy impacts the behavioral expectation to utilize Bitcoin.

Social Influence: This is how much a person sees how colleagues, loved ones/individuals of huge significance assume that people should utilize the innovation (Venkatesh et al., 2012). Influence from other individuals using Bitcoin will help facilitate the adoption by Ghanaians. Venkatesh et al. (2003) stated that social influence significantly affects the adoption of a technology. Social influence also affects the acceptance of IT (Kijisanayotin, Pannarunothai & Speedie, 2009). Therefore, the researchers postulate that:

P3: Social influence impacts the behavioral expectation in utilizing Bitcoin.

Facilitating Conditions: This is how much a person assumes that a hierarchical and specialized framework (infrastructure) is set up to help utilization of the system (Venkatesh et al., 2012). The unique set of the Bitcoin network will aid the successful adoption by Ghanaians. Venkatesh et al. (2003) stated that facilitating conditions significantly affect the use of a technology. Therefore, the researchers postulate that:

P4: Facilitating conditions impacts the behavioral expectation to utilize Bitcoin.

Hedonic Motivation: This is another build included in the UTAUT2 model. Hedonic Motivation denotes the agony/delight realized from utilizing an innovation (Venkatesh et al., 2012). Ghanaians will adopt Bitcoin if they obtain a positive feeling as a result of using it. Yang (2010) found that hedonic motivation is a critical determinant of an individual's intentions to use a technology. Therefore, the researchers postulate that:

P5: Hedonic motivation positively influences an individual's behavioral expectation in utilizing Bitcoin.

Price Value: This refers to the tradeoff between the benefits of a good or service and the monetary cost of that particular good or service (Venkatesh et al., 2012). The price value of the technology will influence Ghanaians to adopt Bitcoin. The cost and pricing structure may have a significant impact on consumers' technology use (Venkatesh et al., 2012). They also stated that the benefits of using a technology is much greater when the price value is positive than the cost, which will lead to a positive impact on intentions to adopt. In a study conducted by Njuguna (2014) about Bitcoin adoption in developing economies, it was found that the low transactional cost of Bitcoin significantly affects the intention of an individual to use the technology. Therefore, the researchers postulate that:

P6: Price value positively influences an individual's behavioral expectation in utilizing Bitcoin.

Habit: This is how much individuals tend to play out a conduct naturally due to an increased comprehension or learning (Venkatesh et al., 2012). Ghanaians will intend to adopt Bitcoin if it becomes a necessary requirement in purchasing some products online.

Therefore, the researchers postulate that:

P7: Habit influences an individual's behavioral expectation in the utilization of Bitcoin

New Constructs

To be able to accurately determine and explain why individuals adopt a technology from a developing economy's perspective, the researchers introduced two additional constructs to add to the existing model. Trust and Perceived risk were the extra constructs added to the UTAUT2 model by the researchers. Consideration of the development of the UTAUT2 model is bound by Bagozzi (2007) and Venkatesh et al's. (2007) submissions which wishes to extend the first model in order to utilize it in various settings (Roos, 2015).

Trust

Rousseau, Sitkin, Burt & Camerer (1998) stated that trust is an individual's readiness in relying upon other individuals gathering in light of their attributes. The eminent sociologist Georg Simmel asserted that trust is the premise of any financial request (Altmann, 1903).

In any case, researchers, for example, Komiak & Benbasat (2004) have seen trust from the passionate perspective and characterized it as the degree to which an individual feels secure and sure about depending on the trustee. Ennew & Sekhon (2007) have characterized trust as a person's eagerness to acknowledge defenselessness on the grounds of inspirational assumptions about the aims or conduct of another in a circumstance described by reliance and risk. This definition joins both the enthusiastic and intellectual

measurements of trust. Folkinshteyn & Lennon (2017) in a study about Bitcoin adoption found out that trust is highly important during transactions between the two parties. In this manner, Ghanaians trust that the Bitcoin infrastructure is secured, and level of risk associated with it is minimal, hence aiding in its adoption. In another study, Zarifis et al. (2015) also found that trust is very essential and affects the adoption of digital currencies of which Bitcoin is part of. Therefore, the researchers postulate that:

P8: Trust positively influences an individual's behavioral expectation in utilizing Bitcoin.

Perceived Risk

Perceived risk in a user's conduct is characterized as any activity of a buyer that may prompt offensive results (Lopez-Nicola's & Molina-Castillo, 2008). Different investigations have considered perceived risk as the user's expectations of misfortune in quest for a desirable result. In light of the previous definition, perceived risk is a multidimensional construct comprising of four measurements: budgetary(financial), mental, execution and social misfortune (Ho & Ng, 1994; Keat & Mohan, 2004; Lu et al., 2005) or danger of losing individual control (cash, time) and danger of framework disappointment.

Nonetheless, Pavlou (2003) and Shin & Kim (2008) in their findings, contend that hazard ascends from people subjectively and is hard to catch unbiasedly. The division of perceived risk into sub-measurements in some cases are not precise and can't survey all the applicable danger measurements, particularly when the study concentrates on unsafe systems like transacting online (Wanget al., 2003). Ermakova et al. (2017) in their study found out that perceived risk of theft or loosing Bitcoins through an attack or due to human error negatively affects an individual's ability to adopt the technology. Perceived risk of loss as a result of dishonesty due to the use of bitcoin heavily affects the adoption of the technology (Folkinshteyn & Lennon, 2017). Therefore, the researchers postulate that:

P9: Perceived Risk positively affects the behavioral expectations in utilizing Bitcoins.

P10: Intention to adopt Bitcoin directly influence the Actual adoption of Bitcoin.

Methodology

The proposed research utilized the qualitative approach through interviews. Due to the exploratory nature of this phenomenon, the qualitative approach was deemed fit, hence its usage.

The reason for using this instrument is to track the perceptions of Ghanaians who use bitcoins and to assess their level of knowledge and also discover challenges faced by them.

The target population for this study was bitcoin community in Ghana. The sampling method used was purposive sampling since it is extremely difficult to find bitcoin users especially in Ghana. The convenience sampling made use of respondents who were available and willing to partake in the study.

Data Collection Methods

The method of data collection for this research was evaluation of primary and secondary data which included academic journals, thesis and reports published previously. The instruments used for the data collection were interviews and phone calls.

The essential information sources included twelve (12) respondents, from educational institutions and industrial conferences involved in Blockchain and Bitcoin development in Ghana. These respondents consisted of three faculty members, two bitcoin traders, one blockchain developer, one financial expert, and five student entrepreneurs. The interviews were recorded, transcribed and presented to respondents to make corrections where necessary.

Data Analysis

The evidence gathered were presented in relation to the constructs of the model. This allowed for the easier drawing of themes from the response gathered from the respondents. This enabled the researcher to map out similarities and contrasts from the results obtained in relation to the adoption of bitcoin.

SOLUTIONS AND RECOMMENDATIONS

Findings and Discussion

The purpose of this study was to explore the determinants of Bitcoins adoption among Ghanaian individuals and to assess the nature of the usage of the Bitcoin technology payment preferences in transactions.

Respondents judged the use of Bitcoin as extremely positive. Regardless of the moderately low awareness rate, all respondents showed that they will keep utilizing Bitcoin on the premise that the effort expected to utilize it, the facilitating conditions and the performance of the use of Bitcoin will continue as before.

The principal concern communicated by the few respondents were the value fluctuations of Bitcoin. Despite the fact that they saw Bitcoin to have certain advantages over other payment methods, a few respondents expressed that Bitcoin represented some type of hazard in its use, which in this way affected their choice to keep utilizing it. This study explored the hypothesis that the greatest difficulty confronting Bitcoin appropriation among prospective users was the assumed challenges as regards understanding the idea of Bitcoin and how it can altogether decrease the cost of exchanges.

Another worry of a few respondents on the issue of trust were featured as powerless focuses for the appropriation of Bitcoin. Trust was found as an essential prerequisite for the proposed continuation to utilize Bitcoin.

Most respondents likewise esteemed decidedly the Price estimation of Bitcoin. They communicated they want to utilize it more because of the way that the estimation of Bitcoin continues expanding due to its appeal. Heintze (2014) said this enables them to accumulate Bitcoins to push the costs up in view of speculations.

Performance Expectancy

Three topics related to the performance expectancy of Bitcoins were mentioned. Quick transactional operations were one of the three most frequently mentioned by the respondents. They expected that since transactions are peer-to-peer, it will increase the effectiveness of Bitcoins and enhance its usefulness.

However, the perceptions of the respondents concerning the fulfilment of these expectations were very diverse. Respondents were positive about the added value of the use of Bitcoins:

Due to the use of Bitcoins, I am able to do transactions faster by just scanning the QR code of the recipient address, which definitely saves time and its of added value.

Improved productivity: Respondents expected to accomplish tasks more quickly and consequently achieve an improved productivity by the use of Bitcoins. A respondent stated:

Bitcoin offers one thing that anyone can hope for, that is the freedom to perform transactions without worrying about limitations. I am able to do more transactions with bitcoins in less time.

This idea came about from the expectation that the Bitcoins enable faster transaction processing which ensures the ability of users to process more transaction, which should have been less time consuming.

A cost-effective application: Respondents claimed that Bitcoins should be of added value when using it and that possible financial benefits of the Bitcoins would play a major role in the actual use of the currency. However, all respondents who valued the cost-effectiveness of Bitcoins revealed that it is very cost-effective and profitable. A respondent indicated:

The cost of transactions when using bitcoins is very low compared to other payment options.

As seen in our study, it has been established that Performance expectancy has been a major influencing factor which significantly affects the intention to adopt Bitcoin. This was affirmed by studies conducted by (Zhou et al., 2010; Venkatesh et al., 2012; Chang, 2012) where it was found that performance expectancy significantly affects an individual's ability to adopt and use a technology.

Effort Expectancy

Alongside the performance expectancy of the use of Bitcoins, some topics related to the effort expectancy of the use of Bitcoins were discussed. Respondents mentioned the user-friendliness of Bitcoins as one of the requirements for their intended continuation to use it.

Learning to use the Bitcoins: The effort expectancy of the respondents related to this topic was relatively low. For example, a respondent said:

There was no difficulty when learning to use Bitcoins. It was user friendly and I could operate it on my own with the little assistance given by the Bitcoin wallet application, which did not require any special IT knowledge.

However, there was no consensus about the actual effort needed to learn how to use Bitcoins. Respondents stated these differences to the amount of IT experience and the user-friendliness.

Daily use of Bitcoins: The effort expectancy regarding the daily use of Bitcoins was also relatively high. For example, a respondent said that:

I expected the Bitcoins to be easy to use. Using it was clear and I really understood how it works.

The actual effort needed to access and use Bitcoins daily was very little:

I don't struggle when using Bitcoins and you don't spend a lot of time using it. Everything is fast and simple.

Another respondent said:

The experience has rather been much more effortless.

Effort expectancy in the use of Bitcoin was very important and was found out that it significantly influences an individual's intention to adopt and use Bitcoin. This is in line with the findings from studies (Helena et al., 2010; Deng et al., 2011; Venkatesh et al., 2012) which revealed that Effort expectancy is a major predictor and significantly impacts the behavior of an individual in IT adoption and innovation.

Social Influence

With this construct, two different topics were discussed during the interview about the social influence of Bitcoins.

First of all, the view of colleagues and clients regarding Bitcoins was very diverse. The difference in opinions might be related to the local clients. A respondent indicated that:

My colleagues use bitcoins to increase value since the value of bitcoins is rising every day and I also noticed that Bitcoins was mainly useful when I am not doing physical transactions like paying for stuff overseas. Its less useful for local clients or clients that I physically meet to transact business with.

Respondents were also asked about the importance and influence of the views of colleagues and clients on their own opinions. The respondents confirmed the importance and influence on their own opinions as opposed to a minority of the respondents who expressed a different view:

All my colleagues who are using bitcoin mostly feel the same way I do. They speak highly of it and it encourages me to use it even more. The opinions of my colleagues are important, in the sense that they give me more information on the market value of bitcoins and whether to buy more or less coins because some of them are Bitcoin merchants.

Another respondent stated:

I'm still learning new things about bitcoins. My organization has also been helpful and provided invaluable motivation.

Almost all respondents felt supported by their colleagues and clients. This support was in the form of information sharing about the value of the coins and other Bitcoin investment opportunities. In this study, Social influence has been recognized as an influencing factor in Bitcoin adoption as confirmed with studies (Venkatesh et al., 2003; Kijisanayotin et al., 2009; Venkatesh et al., 2012) which also found out that Social Influence significantly influences the adoption of a technology.

Facilitating Conditions

Most topics which were mentioned by the respondents during the interview related to the facilitating conditions of Bitcoins.

Resources and knowledge necessary to use Bitcoins: It was remarkable that the respondents possess knowledge as well as the resources necessary to utilize Bitcoins. Moreover, a respondent mentioned to have had the knowledge, but not the appropriate device to use Bitcoin.

I lost my smartphone and had no computer; therefore, I shared a computer with a colleague who was my roommate. I did receive an android phone running OS 4.0, but the Bitcoins wallet application did not function properly on the android phone.

Attitude towards using technology: Respondents indicated to be very positive about working with technology. In addition, doing business with the aid of technology is the future according to them. A respondent stated:

Technology provides us with means to approach problems differently. It gives us different ways of solving complex problems more effectively and efficiently. In today's world, the use of technology has become a common practice because it helps boost productivity. I do a lot of buying online and websites nowadays have integrated various payment systems on their websites. That's how I noticed that Bitcoin wallet addresses or QR codes can be integrated with the site which would fit well with Bitcoin users.

Changed behavior: Respondents highlighted the fact that it was easier letting go of payment methods and developing a positive behavior towards the use of Bitcoins. This situation was as a result of the fact that they were looking for innovative and cost-effective methods of managing money transactions.

The knowledge and resources needed for Bitcoin, attitude to the technology and the behavior exhibited by an individual is very important for the actual use of Bitcoin. Facilitating conditions was found to significantly impacts and plays an important role in Bitcoin adoption in this study. This is consistent with studies (Venkatesh et al., 2003; Venkatesh et al., 2012) which found out that Facilitating Conditions emerged as a predictor and an influencer in adopting a technological innovation.

Price Value

Transactional cost: Respondents revealed that the cost incurred from Bitcoin transactions are relatively cheaper and reasonably priced which provides significant savings compared to other forms of payment. A respondent accounted that:

Currently there are either no fees, or very low fees within Bitcoin payments.

Benefits enjoyed from the usage of Bitcoin has been emphasized in studies as a major predictor of Bitcoin adoption. This study found out that price value was significant influencer in the adoption of the Bitcoin innovation thereby affirming the findings by (Venkatesh et al., 2012; Njuguna, 2014).

Hedonic Motivation

Feedback from clients: Respondents reported positive feedback from customers on how Bitcoin is easy to use; they found using it enjoyable and derived great pleasure when transacting with Bitcoins.

The user-friendly nature of Bitcoin makes it an enjoyable activity which provides satisfaction for an individual and actually impacts the intention to adopt the Bitcoin innovation. This study revealed that Hedonic motivation contributed for the adoption of Bitcoin hence affirming studies (Yang, 2010; Venkatesh et al., 2012) which also found hedonic motivation to be a significant influencer and predictor in technology adoption.

Habit

Respondents stated that the use of Bitcoins had not become a habit for them since most people do not recognize it here. Speaking of addiction, respondents quickly stated that they are not in any way addicted to Bitcoins and it is not obligatory that they use it for every transaction.

In this study, Habit was found not to be a predictor of the Bitcoin adoption from a developing economy's perspective. Individuals in developing economies tend to have a habit of using physical currencies for everyday transactions. This is in contrast with studies (Venkatesh et al., 2012) that found out that Habit significantly influences the adoption of the Bitcoin innovation. This is in relation to the lack of understanding and convenience on the part of retailers in developing economies. Paying for goods and services in developing economies are transacted with physical currencies and has become a habit of individuals in developing economies to rely more on the use of paper money to fulfil financial obligations.

Trust

Integrity: Respondents asserted the fact that since the bitcoin network is global and does not belong to a particular person, integrity is assured in the sense that transactions are recorded in a public ledger which is seen by everyone on the network. Thus, everything stays synchronized and nothing is altered. This makes the platform perfectly honest and truthful.

Personal Information: Personal details of the owners are not revealed to anyone. A respondent indicated that:

The owner has full control of his money because there is no central authority in the Bitcoin network. It gives you the freedom to have control over your own money. The fact that personal information is not required for transactions also influences my decision to opt for bitcoin for my transactions with the rise in internet fraud, it is necessary to protect any personal information whenever possible.

Trust in a system is very important indicator and predictor in the adoption of a technology (Rogers & Shoemaker, 1971). Trust in this study was found to be very essential for individuals and low levels of trust hinders the intention to adopt Bitcoin. This is true as studies (Folkinshteyn & Lennon, 2017; Zarifis et al., 2015) confirm that trust in a system ensures a successful adoption of Bitcoin therefore making it a significant factor in the adoption of an innovation.

Perceived Risk

Some respondents stated that transactions with Bitcoin are secure and safer than other forms of transactions. The security features in Bitcoin does not allow unauthorized use due to its cryptographic nature making it hard to break. A respondent said that:

In spite of the fact that Bitcoin is absolutely digital, it can be kept secure in analog form. Paper wallets can be utilized to store Bitcoins offline which fundamentally diminishes the odds of the cryptocurrency being stolen by programmers or PC infections.

Others were skeptical and felt insecure about it. A respondent said:

Well, yes, with the advancement of technology and hackers all over, I still have a little bit of reservations on how secured the platform can be.

It was found in this study that Perceived risk is an important contributor for the adoption of Bitcoin as a result of the secureness and how rigid the Bitcoin system is. This confirms the findings from studies (Wang et al., 2003; Ermakova et al., 2017; Folkinshteyn & Lennon, 2017) that suggested that perceived risk significantly influences the adoption of a technological innovation.

Intention to Use

All respondents proposed to keep utilizing Bitcoin on the premise that it was less expensive while doing exchanges, easy to use and straightforward, and was exceptionally secure compared with different types of payments. Besides, it was recognizable that an expanded profitability rate and an expanded viability of utilizing Bitcoin was deemed normal by respondents. Although, every one of them expressed to have the assets and learning important to utilize Bitcoin, yet some remarked adversely on its similarity issues. Moreover, it was interesting that respondents who needed to expand their utilization of Bitcoin were supported by their colleagues.

Also, it was surprising that most respondents had knowledge of Bitcoin and that all their hopes in terms of ease of use were met although the real push to utilize it was low.

Table 2 below summarizes the findings and provide lessons obtained from the findings:

FUTURE RESEARCH DIRECTIONS

Any research study, unavoidably, is expected to experience some limitations, and this research is no exemption. The following are a few limitations that have been distinguished in this study with proposed future research directions.

The study was restricted to Ghanaians in the capital city (Accra) as a result of the ease of finding respondents and information that the researchers expected to assemble. Consequently, future research ought to be completed utilizing a wider geographic area in Ghana. Also, this study adopted a qualitative approach interviewing twelve respondents thus making it difficult to generalize the findings in the Ghanaian context. In addition, the unit of analysis was done at the individual level. Future study can conduct a quantitative survey covering more firms to ascertain the adoption of Bitcoin at the firm level in Ghana.

Table 2. Lessons obtained from findings

Construct	Proposition	Lessons
Effort Expectancy	Effort expectancy impacts the behavioral expectation to utilize Bitcoin.	Effort expectancy in the use of Bitcoin was very important and was found out that it significantly influences an individual's intention to adopt and use Bitcoin.
Performance Expectancy	Performance expectancy has a generally solid consolation on an individual behavioral aim in utilizing Bitcoin.	Quick transactional operations, Improved productivity and a cost-effective application impacts on the intention to adopt Bitcoin
Facilitating Conditions	Facilitating conditions impacts the behavioral expectation to utilize Bitcoin.	The knowledge and resources needed for Bitcoin, attitude to the technology and the behavior exhibited by an individual significantly impacts and plays an important role in Bitcoin adoption
Social Influence	Social influence impacts the behavioral expectation in utilizing Bitcoin.	Social influence through information sharing about the value of the coins and other Bitcoin investment opportunities from colleagues and clients influences Bitcoin adoption
Habit	Habit doesn't influence an individual's behavioral expectation in the utilization of Bitcoin	Individuals in developing economies tend to have a habit of using physical currencies for everyday transactions.
Hedonic Motivation	Hedonic motivation positively influences an individual's behavioral expectation in utilizing Bitcoin.	The user-friendly nature of Bitcoin makes it an enjoyable activity which provides satisfaction for an individual which actually leads to the intention to adopt the Bitcoin innovation.
Price Value	Price value positively influences an individual's behavioral expectation in utilizing Bitcoin.	Transactional cost of Bitcoin encourages its adoption due to its cost effectiveness
Trust	Trust positively influences an individual's behavioral expectation in utilizing Bitcoin.	Integrity and the protection of personal information facilitates the adoption of Bitcoin
Perceived Risk	Perceived Risk positively affects the behavioral expectations in utilizing Bitcoins.	The secureness and the rigid nature of the Bitcoin system contributes significantly to its use.

Drawing from the findings of the study, the researchers recommend that policy makers (government) should provide a legal and regulatory framework in the implementation of a national policy on the use of bitcoins in the country.

CONCLUSION

This study seeks to investigate the nature of Bitcoin adoption in Ghana and also explored the determinants of Bitcoin adoption as a payment option in Ghana through the lens of UTAUT2.

Findings from our analysis indicate that majority of individuals in Ghana are aware of the Bitcoin technology and have considerable knowledge of how to use this innovation. This is so as the use of Bitcoin doesn't require much therefore individuals in the country are gearing towards its use. In addition, individuals, business owners and business partners preferred the bitcoin option as it reduces the cost of money transactions which allowed them to consider it as a payment method for international transactions. Also, availability to Bitcoin merchants in the capital city (Accra) allowed easy access to individuals who wanted to buy and sell their Bitcoin therefore encouraging the use of the technology.

Again, in this study, it emerged that the determinants of Bitcoin adoption in the Ghanaian context are Performance Expectancy, Effort Expectancy, Social Influence, Hedonic Motivation, Price Value, Trust

and Perceived risk. Evidence also showed that Facilitating conditions directly influence the actual adoption of Bitcoin. However, this study established that Habit had no effect on the intention to adopt Bitcoin.

Taking everything into account, the utilization of Bitcoin is considerably gaining recognition and enthusiasm in Ghana. This observation is affirmed by Ted Owusu Duodo (CEO of PMCedis Capital) who reveals that “the demand for bitcoin in Ghana is very high. But, in general, very few people know about Bitcoin. The people who are into it are mostly the youth and among them, the demand is very, very high” (Scott, 2016). It was additionally ascertained that Bitcoin decreases the cost of exchanges. Bitcoin were delivered as money to be free of any central authority, transferable electronically, pretty much in a split second, with low exchange expenses, when contrasted with conventional assets exchange administrations like Western Union and PayPal. Additionally, the challenges explored the appropriation of Bitcoin as another innovation basic to new advances. Significant mindfulness and preparation should be done to the potential clients of the innovation to ease utilization and diminish the protection from change that may be caused by dread of progress.

KEY TERMS AND DEFINITIONS

Bitcoin: A computerized and worldwide form of money. It enables individuals to send or receive cash over the web, even to somebody they don't know or don't trust.

Blockchain: A distributed record or database of exchanges recorded in a dispersed way, in a network of computers.

Cryptocurrency: A virtual cash intended to fill in as a mode of trade.

Cryptography: A strategy for encoding data in a specific way with the goal that those for whom it is planned can peruse and process it.

Payment Gateway: An online service that facilitates cashless transactions.

Peer-to-Peer: A distributed service whereby one person communicates with another, without intermediation by an outsider.

Proof-of-Work: An algorithm used to affirm transactions and produce new blocks to the chain.

INTRODUCTION

Concerns in the area of cybersecurity have recently been placed under the spotlight, particularly so when 2017 saw a substantial number of cyberattacks and security breaches across the world (Graham, 2017; Leech, 2017). The disruption and costs associated with cyber threats are also increasing exponentially over time, and have rendered such threats as one of the major concerns for many developed countries (Drzik, 2018; World Economic Forum, 2018).

When successful, the consequences of cyberattacks can be profound and manifold. At the individual level, for instance, confidential and sensitive data can be compromised, financial losses can occur, and essential operations can be disrupted (Accenture & Ponemon Institute LLC, 2017; Tham, 2017a). On the wider macro level, the malicious access into computer and network systems can compromise and cause the collapse of “critical national infrastructures (such as energy, transportation, government operations) or to coerce or intimidate a government or civilian population” (Lewis, 2002, p. 1). With the detrimental effects of cyberattacks, it is vital that these cyber threats are managed effectively, for which the present chapter will serve to shed light on the weakest player in the maintenance of cybersecurity – humans.

UNDERSTANDING THE WEAKEST LINK IN CYBERATTACKS: HUMAN BEHAVIOURS

Cyberattacks can be perpetuated via two means: (1) system-centric approach, where perpetrators exploit the technical vulnerabilities of a computer or network system to conduct an attack, and (2) user-centric approach, where negligence or mistakes of the computer users facilitated the execution of cyberattacks (Neupane, Rahman, Saxena, & Hirshfield, 2015). However, successful cyberattacks in reality are often a result of the latter, in which human errors rather than technological shortcomings are the main cause of concern (Kelly, 2017; Tasman-Jones, 2016). According to Symantec, 97 percent of malware attacks in 2016 targeted people and their poor online behaviours, with only the remaining three percent attributed to actual flaws in the network security system itself (Bennett, 2017).

DOI: 10.4018/978-1-5225-9715-5.ch065

Also known as social engineering, perpetrators commonly employ the method of “hacking humans” – rather than the system – by exploiting poor cyber behaviours to gain a backdoor in computer systems and networks (Choo et al., 2016). It encompasses deceiving and psychologically manipulating the victims into divulging confidential information, and/or getting them to perform certain actions that facilitate the execution of cyberattacks. For instance, the social engineering technique of “phishing” works because of the meticulously-crafted email messages that encourage recipients to click on the weblinks or download attachments that are malicious in nature (Lord, 2017; Tham 2017). In 2017, many ransomware attacks targeted at organisations had been caused by successful phishing attempts on unanticipating and careless employees, mainly through their emails or media (Jay, 2018).

Should one exercise caution, such phishing attempts may be avoided as poor human behaviour in the cyberspace forms the core of why many such cyberattacks are successful in the first place (Bennett, 2017; Fallows, 2011; Hadlington, 2017). As what Andy Waterhouse, EMEA Director at RSA Security (cited in Bennett, 2017, p. 12) had commented,

It is not just about silly errors but often a lack of training and understanding of the implications of clicking on a malicious link, going to a risky website or even setting up a service on a public cloud service without looking at the security implications.

The endeavour to combat one’s susceptibility to cyberattacks involve a long process of understanding the specific attributions that contribute to this susceptibility, as well as the necessary follow-up actions needed to be done to manage the threats. Approaches to mitigate the cyberattacks therefore goes beyond the protective capabilities of sophisticated technological solutions (Conteh & Schmick, 2016; Goldman, 2013), such as antivirus software and firewalls, and have to include human-centric measures.

UNDERSTANDING HUMAN-CENTRIC MEASURES

Importance of Good Cyber Hygiene to Manage Cyber Threats

Perpetrators are constantly searching for the weakest link in the computer or network system, in order to gain quick and easy but unauthorised access into these areas (Ashiq, 2015). Humans are unfortunately very much the weakest link in cybersecurity, because of their risky behaviours in the cyberspace (Vishwanath, 2016). A 2017 survey conducted by the Cyber Security Agency of Singapore (CSA), for instance, revealed that many people exhibit poor behaviours (e.g., using the same password for both personal and work accounts, not using two-factor authentication, not installing security on mobile phones, not running virus checks for files and devices before opening them) on online platforms that put themselves and their organisations at risk of cyberattacks (CSA, 2017b).

If poor human cyber behaviours are indeed the main cause of successful cyberattacks, then managing these behaviours should reduce one’s vulnerability towards cyberattacks. To do so, there is a need to reduce risky online behaviours as well as improve one’s cyber hygiene behaviours.

The Value of Cyber Hygiene Behaviours

Protective cyber behaviours are known as cyber hygiene behaviours. Just as how people brush their teeth and take showers to maintain their basic hygiene level and health, cyber hygiene practices are similar except that they take place in the cyberspace (Symantec Corporation, 2017). Cyber hygiene revolves around the implementation of cybersecurity ‘best practices’ to protect and maintain one’s online ‘safety’ and ‘health’ whilst using the computer and internet. It focuses on individual responsibility to perform the identified best practices, rather than depending on the technical protection measures against cyber threats (Aldoriso, 2018; Ashiq, 2015). Some examples of cyber hygiene practices include using an anti-virus software, activating firewalls, updating the operating system, wiping the hard drive, and using complex, unique passwords (Symantec Corporation, 2017).

The many years of effort to educate people on these protective measures¹ have seemingly produced limited results because people are generally still not engaging in adequate cyber hygiene practices. It becomes imperative to explore this phenomenon of non-action, and identify the what’s and why’s of not adhering to cyber hygiene practices despite the obvious value of these behaviours.

Awareness Does Not Equate to Frequency of Cyber Hygiene Practices

It is vital that people do not just know about cyber hygiene practices, but are also proactively undertaking such behaviours to protect themselves from cyber threats. The conventional understanding is that knowing how to and why one should engage in a certain behaviour should lead to the actual execution of the behaviour. However, awareness of cyber hygiene practices does not necessarily translate to its behavioural manifestation. People fail to follow cyber hygiene practices despite becoming increasingly aware about cybersecurity issues (Schick, 2018).

Understanding Poor Online Behaviours Based on Insights From Cyber Hygiene Surveys

Surveys conducted on the frequency of cyber hygiene practices of individuals across the world reveal similar trends. In the United States, the Ponemon Institute conducted a “The Cyber Hygiene Index: Measuring the Riskiest States” research and found that Americans display risky cyber habits (e.g., not downloading and using anti-virus software) despite being aware that they should not do so (Moffitt, 2018). Organisational employees were also engaging in risky behaviours (e.g., clicking on unverified links) despite fears of data breach, according to a survey by OpenVPN in America (Abel, 2018).

Findings from overseas surveys have been observed in Singapore as well. In a 2017 cyber hygiene survey² (CHS) conducted by the Home Team Behavioural Sciences Centre (HTBSC), results revealed that individuals tend to know why they should engage in good cyber habits and how to do them, but they are not really doing it³. With that, the 2017 CHS had also identified several cyber hygiene behaviours that people showed both high awareness of and high frequency in. This included checking the header of an incoming or new email, not clicking on hyperlinks from unknown senders, as well as using ad-block tools to block pop-ups.

Knowledge should stimulate constructive cyber behaviours, just as how education is needed to inform people the why’s and how’s of doing something. Yet, the discrepancy between awareness and frequency of cyber hygiene practices is worrying, because it highlighted underlying concerns that go beyond simply what education and information can do. The examination of motivations underlying this

phenomenon of non-action is henceforth critical, since it may contribute to efforts to improve individuals' cyber hygiene levels.

THERE ARE MANY PSYCHOLOGICAL REASONS FOR INACTION OF CYBER HYGIENE PRACTICES

The reasons for inaction of cyber hygiene practices cannot be attributed to a single factor. From a psychological perspective, various reasons can be identified to explain why people are not taking proactive steps to protect themselves from cyber threats, despite knowing the importance of doing so.

Lack of Individual Responsibility

The sense of individual responsibility can determine whether people will take necessary steps to protect themselves from cyberattacks. Responsibility is found to be related to action (Coleman, 2012), where people with a low sense of individual responsibility tend to be less motivated to engage in safe cyber hygiene practices.

In fact, cybersecurity research in organisational settings have demonstrated that people usually engage in these protective practices only if relevant social others are doing it (e.g., peers, colleagues, direct superiors), or simply if they are likely to get caught for not doing so (Herath & Rao, 2009). A 2016 survey conducted by HTBSC on 'Perceptions of National Resilience'⁴ further supported the notion of the lack of individual responsibility for dealing with cyberattacks. Far from seeing it as a responsibility that one should undertake, 64 percent of the respondents perceived that it is the government's duty instead to protect them from a cybersecurity crisis.

Low Cyber Risk Perception and Complacency

Optimism bias refers to the tendency for humans to underestimate the likelihood of negative events happening onto them (Sharot, 2011). In the context of cyber threats, it can result in a false sense of security, since individuals are likely to perceive themselves to be 'invulnerable' to attacks (Shah, 2014). Low cyber risk perception and complacency are likely to cause people to disregard cues of danger, behave recklessly online, and not take precautions to protect themselves from cyber threats.

The lack of experiences may further render individuals incognisant of how real the threat and consequences of cyberattacks are. Indeed, the absence of 'painful lessons' makes it difficult for one to justify why they should learn, engage in efforts, as well as mobilise valuable resources to build some degree of cyber defence (Siau, 2017). Furthermore, people may not necessarily engage in appropriate behaviours, unless they deem that the cyber threats will occur to them and that these threats are targeted at their personal concerns (Lee, Larose, & Rifon, 2008).

Lack of Usability Security

The implementation of cyber security measures will increase one's protection against cyber threats. However, it may also reduce the ease of use of technology (i.e., speed, convenience) and one's work productivity and efficiency on the device (Bruzzeze, 2015). This is also known as the lack of usability security. When people realise that they may experience reduced speed and convenience, they are less likely to engage in good cyber hygiene practices even if it means acquiring tougher security levels.

For instance, while a newer mobile phone operating system (OS) patch provides greater and more effective security measures, people may hesitate to update their OS if it slows down the processing speed of their phone. Additionally, if the process of updating the software of a computer is a slow endeavour and there are many computers that require updating, it could result in substantial opportunity costs between downtime and financial profits for the organisation. Consequently, the company may be tempted to forgo the benefits of the latest computer software update, and instead dedicate time to pursue financial earnings. Thus, whether or not individuals engage in cyber hygiene practices does depend on the consequences and their attitude towards it. If consequences are positive, a favourable attitude is likely to transpire, thereby increasing the likelihood that the cyber hygiene practice will materialise.

Difficulty in Learning and Implementing Good Cyber Hygiene Habits

The more technical a cyber hygiene practice is to perform, the less 'common sense' it becomes (Ng, 2017). The harsh truth is that if a cyber hygiene practice is perceived to be difficult to do, an individual naturally will be less likely to adopt that practice. For instance, checking if the secure sockets layer (SSL) is present is important before one conducts financial transaction via the internet. SSL refers to the lock icon beside the web address at the address bar of an internet browser, which is an indication as to whether a website is securely connected to the web server or not (GlobalSign, 2018). However, it can be a challenging thing to do if people are not aware of what exactly is SSL, or the steps needed to check the quality of the SSL certificate. Consequently, people may become less likely to check if the SSL is present and/or the quality of the SSL certificate.

On the opposite spectrum, cyber hygiene practices that are easy to execute and commit to are more likely to see a higher frequency of behavioural manifestation. This could be a potential reason for the high awareness and frequency of several behaviours, including the checking of email header and using ad-block tools to block pop-ups, since they do not require significant conscious effort to do so.

Lack of Others Who Are Also Engaging in Cyber Hygiene Practices

Normative beliefs focus on whether a person feels pressured to do something or not, based on what he or she observes others to be doing (Ajzen, 1991, 2002). In other words, individuals are likely to feel the need to engage in certain cyber practices simply because others are doing it. According to Herath and Rao (2009), the expectations and behaviours of relevant others, including superiors and peers, are significant influences on individuals' cyber security behaviours.

The awareness of why people engage or do not engage in certain cyber hygiene behaviours will be useful to inform and shape cybersecurity measures. People exhibit inaction for distinctive reasons, which perhaps then, lead to the requirement of a myriad of human-centric solutions, on top of technical security measures, to improve human cyber behaviours and reduce one's susceptibility to cyber threats.

IMPLICATIONS FOR DESIGNING HUMAN-CENTRIC APPROACH TO COMBAT CYBER THREATS

The reasons as to why people do or not do certain cyber hygiene practices differ from person to person, and even context to context. The development of measures to improve problematic cyber behaviours should henceforth be highly targeted and relevant, depending on the individuals' needs and the current climate of cyber threats. The following are some implications for designing human-centric measures against cyber threats.

Education on Cyber Threats Must Continue

Education is critical to help people understand why it is necessary for them to engage in good cyber habits. Consequently, it should prompt people to act to protect themselves from cyber threats, thereby reducing the inconsistency between people's awareness of cyber hygiene practices and how often they perform them. More importantly, besides informing people about the current climate of cyber threats, education should also include (i) how cyber perpetrators target victims (i.e., exploiting the lack of good cyber behaviours) as well as the common methods they use to execute their attacks (i.e., social engineering), and (ii) reasons that reduces the likelihood of practising these proper cyber practices so as to draw attention to this area of concern.

Regular mandatory cyber hygiene or cybersecurity programmes could be offered to people, such as the employees of an organisation or students from an educational institution. These trainings can serve as an effective platform to instil knowledge, address any misconceptions on cybersecurity issues, or for individuals to share and learn from one another on their experiences, if any, dealing with cyber threats. Participants do not have to be an actual victim before they can learn. The sharing and illustration of authentic experiences can aid internalisation of the seriousness of the cyber threat, whereby the fidelity of the victim's voice reinforces how real the threat and consequences are.

Tailor Outreach Messages

Various sources of information can be condensed into digestible bite-sized knowledge and contribute to educational material. Local and international cyber threats can be studied holistically to identify new or emerging trends. Primary data may also be gathered to contribute to teaching resources, including interviews with incarcerated attackers to understand common modus operandi and the human vulnerabilities they target to facilitate their attacks.

Outreach messages ideally should be tailored to different societal groups, according to various demographic markers such as age – i.e., the types of cyber threats affecting the young and the old may differ, dictating the need to introduce tailored measures. Furthermore, targeted messages may help particular groups to understand and better relate to the current climate of cybersecurity using appropriate case examples and interventions. When the target audience understands why cybersecurity is an issue for them, it becomes easier for them to change their attitudes. Constant reminders are necessary as well, since people are likely to forget and become complacent over time. Different modes of transmitting these messages can be utilised. For people who particularly do not have sufficient time to read their emails or cyber security advisories, sending concise email reminders on the importance of practicing good cyber habits is a feasible alternative.

There is also the need to revise educational messages occasionally, in order to recapture people's attention over time (Belch & Belch, 2009). An underlying reason for doing so arises from the concern that constant exposure to the same messages can ultimately result in individuals being desensitised – or numb – towards these messages (So, Kim, & Cohen, 2017).

The Need to Nudge Humans to Engage in Cyber Hygiene Practices

Education by itself is clearly not sufficient. This was seen in the 2017 CHS results, in which people are still not engaging in important cyber actions despite knowing why or how they should do it. This highlighted underlying issues that goes beyond what education can do.

The nudge theory can be employed to complement outreach efforts. A nudge prompts people to take action by subtly making the decision-making process easier (Chu, 2017). The decisions that an individual have to make, or the thought processes that they have to undergo first, can be complicated enough such that it prevents or slows down the occurrence of engaging in good cyber behaviours altogether. Automation, for instance, is a nudging method whereby people are automatically required to do something unless they opt-out of it (if there is an opportunity to do so). In the context of cyber hygiene practices, this could mean setting various practices as a default feature or behaviour (i.e., natural 'opt-in') that people have to engage in when they use the computer or internet. As a result, it removes the need for people to proactively undertake constructive cyber practices. Higher participation and compliance to regulations are consequently more likely to follow as well (Blau, 2017).

Automation can also make certain practices less difficult or tedious to do (e.g., reduces the amount of time, effort, and knowledge needed to perform it), thereby increasing the likelihood that people will eventually engage in these protective measures.. When barriers to action (e.g., technical details) are removed, a certain action becomes easier to carry out.

Conduct Red-Teaming Exercises

The objective of red-teaming exercises is to “obtain a realistic level of risk and vulnerabilities against your technology, people and physical/facilities” (RedTeam Security Consulting, 2016, p. 1). One method to do so is to invite white hats to hack into these systems, therefore checking the resiliency of an organisation's computer and network systems. In other words, a cyberattack will be purposefully – with no malicious intention – conducted without employees' knowledge of the exercise, to reveal the ways in which cyber perpetrators can exploit to enter the organisation's computer and network systems. This includes identifying both human and technical vulnerabilities.

The benefit of red-teaming also lies in its capacity to create a level of psychological fidelity, allowing people to experience the effects of a real cyberattack but under safe circumstances with minimal repercussions. According to Boud, Cohen, and Walker (1993), such experiences can help to accentuate the criticality of cyber issues within the organisation. With red-teaming exercises, it is with the expectation and hope that people will be more careful and thus practice good cyber hygiene practices in the future, after experiencing the negative emotions and consequences of a cyberattack.

Nonetheless, there is a need to balance between the endeavour of identifying the vulnerabilities of one's online security system and the potential negative emotional exerted on the “victims” as a result of such exercises. Should red-teaming exercises be conducted, there is a need to provide debriefs to these individuals to help manage their reactions.

Regulations to Ensure Compliance to Cyber Hygiene Practices

Certain cyber threats lay dormant and are not obvious unless a computer or network system is consciously scanned for compromise. Unfortunately, the notion of reviewing these systems on a regular basis may not be welcomed, particularly when the process is time-consuming and effortful. Regulations to drive for consistent audits should hence be implemented. These regulations may also include policies to ensure that people are mandated to engage in other necessary cyber hygiene practices.

Furthermore, detection mechanisms to detect lack of compliance could be developed and executed alongside these regulations. As expressed by Herath and Rao (2009), people will observe rules simply because of the fear of being discovered to be not observing them. To ensure its effectiveness, such detection mechanisms initiatives should be clearly communicated to the employees in advance, and constantly reinforced. A subtler option to get people to start complying with cyber hygiene practices is ensuring that superiors or leaders in an organisation are doing so as well, since people are likely to model after significant others who are deemed to be important characters within the organisation. In the long-run, this may create a culture in the organisation that engaging in good cyber hygiene is common and normal, and that compliance to cybersecurity protocols is indeed necessary.

CONCLUSION

Understanding the nature of human behaviours on the cyber space is critical, given that poor cyber practices on this platform has clearly led to the successful execution of cyber threats. Poor human behaviours of varying kinds offer perpetrators the window to exploit these vulnerabilities to facilitate their attacks, and plenty can be done to help humans engage in better online hygiene practices.

Nonetheless, much more research still needs to be conducted in this area, given its emerging yet imperative nature. More comprehensive studies looking at the relationships between online human behaviours and cyberattacks – or even the modus operandi of perpetrators – will indefinitely be useful. This can shed light on what exactly is critical and needs to be worked on.

It remains clear at the end of the day, that technological vulnerabilities is only just one small reason why cyber threats have proliferated and blossomed today. The role of poor human cyber behaviours cannot be ignored or undermined, because they are a, if not one of the more important, cause of concern.

KEY TERMS AND DEFINITIONS

Cyber Hygiene: Cyber protective behaviours that people engage in whilst on the computer and internet, such as installing and updating anti-virus software.

Cyberattack: A form of cyber threat whereby perpetrators aim to create a backdoor in a computer or network system to gain unauthorised access into these systems.

Optimism Bias: A human tendency where people overestimate the likelihood of good things and underestimate the likelihood of bad things happening onto them.

Social Engineering: The psychological manipulation of victims by cyber perpetrators, in order to get victims to divulge sensitive confidential information, or to perform certain actions that help perpetrators to successfully execute their cyberattacks.

ENDNOTES

¹ Such as Singapore's First National Cybersecurity Awareness Campaign launched by CSA in early 2017 (CSA, 2017a), United Kingdom's GetSafeOnline Campaign (Get Safe Online, 2018) and Cyber Aware Campaign (Cyber Aware, n.d.), as well as Cyber Security Campaign in Hong Kong (Cyber Security Campaign, n.d.).

² In collaboration with social engineering expert Dr Arun Vishwanath from the Department of Communication in University at Buffalo, HTBSC conducted a survey that assesses for various facets of Singaporeans' cyber hygiene. In particular, it assesses for: (1) awareness of cyber hygiene practices, (2) frequency of cyber hygiene practices (a total of 39 different practices were assessed), (3) risk beliefs, (4) phishing knowledge, and (4) reporting behaviour. A total of 404 responses were

collected from the community (using convenience sampling method), with respondents from age 16 to 67 years old.

- ³ According to the CHS, some top problematic cyber hygiene practices (in which people know why and how they should do it), are (in no sequence): using incognito mode or private mode when routinely surfing the internet, create new/unique logins and passwords for all online sign-ins, using a VPN when in an open/public Wi-Fi network, clearing browser cache, creating complex logins and passwords, checking device to ensure that it has the latest OS, software update, or patch, clearing cookies on browser, changing default passwords on all Internet-enabled devices, managing how browser stores passwords, storing logins and passwords on encrypted online password vaults, managing privacy settings on social media platforms, keep virus protection updated, running a virus scan on any new USB or external storage device.
- ⁴ A segment of the 'Perceptions of National Resilience' survey assesses individuals' perceptions of how likely various crisis scenarios will happen in Singapore, and to what extent are individuals, community, and government responsible for responding to crisis scenarios such as cybersecurity crisis. A representative total of 3000 Singaporeans' responses was collected.

INTRODUCTION

Social networking sites (SNS) are, “applications that enable users to connect by creating personal information profiles, inviting friends and colleagues to have access to those profiles, and sending e-mails and instant messages between each other” (Kaplan and Haenlein, 2010:63). Any type of information such as blogs, photos, videos and audio files can exist within these personal information profiles. Therefore, SNS can be viewed as virtual communities that enable on-demand communication and interaction with real-life friends as well as the ability to meet new friends from around the world based on similar interest (Kuss and Griffiths, 2011). The rapid growth in usage of SNS worldwide in recent years, permits its description as a ‘global consumer phenomenon’ (Kuss and Griffiths, 2011). While there are great advantages for the use of SNS, one research by Kuss and Griffiths (2017) suggests that constant usage can create the perception of a need to be online. This may result in compulsive and excessive use of SNS and in some cases give rise to symptoms associated with substance-related addiction. This excessive use of SNS can reduce the productivity of users as well as increase their exposure to cyberattacks. On the other hand, a recent study by Allcott et al. (2019), explores the welfare effects of SNS and discovers that the majority of their sample value access to SNS for four weeks is at US \$100 or more. Therefore, this valuation suggests that consumer surplus for SNS is expected to be in the billions of dollars considering the large number of active users globally. According to Pew Research Center (2018), Facebook and YouTube are the most popular SNS among adults whereas Snapchat and Instagram are the most popular among young adults. Facebook is by far the most popular social networking site globally with 1.52 billion active daily users and 2.32 billion active monthly users (Facebook, 2018).

SNS have become the mainstream communication medium for individuals, especially young people (Holt and Bossler, 2014), and businesses (Culnan et al., 2010). At present there are approximately 4.17 billion internet users worldwide, thus demonstrating a sustained growth from the year 2015 by a quarter. Of these, 3.4 billion are active social media users with a similar proportion of mobile internet users (3.7 billion) according to Statista (2018). However, with the continuous loss of control over personal information that is exposed online, individuals and businesses present easy targets for non-technical attacks

DOI: 10.4018/978-1-5225-9715-5.ch066

ranging from spear-fishing to whaling leading to serious cyber victimization (McAlaney et al., 2018). Cybersecurity professionals agree that this security depends on people more than on technical controls and countermeasures. Recent reviews of cyber security express that no industry sector is invulnerable to cyber-attacks and that the public sector tops the list for targeted security incidents (Benson, 2017). This is largely attributed to the weaker cyber security mind-set of employees. On the other hand, the financial sector, year on year, experiences the highest volume of cyber breaches. These are predominantly aimed at financial gain or espionage. What is common among these rather different sectors is that the attack vector by cyber criminals starts with social engineering. The weakest link in the security chain is still the human element. Irrespective of the market segment, the losses contributing to the current global cost of cybercrime are huge with an estimation of approximately \$600 billion (McAfee, 2018).

Unsurprisingly, the human behavior in an online context has been addressed by researchers for some time. The cybersecurity industry, policymakers, law enforcement agencies and public as well as private sector organizations are yet to realize the factors affecting the risk of online victimization and the impact on individuals and businesses (Taylor et al., 2010). In order to improve cybersecurity practices, there is a need for a discussion acknowledging that cybersecurity is inherently a complex socio-technical system.

This chapter presents an overview of emerging issues in the psychology of human behavior and the evolving nature of cyber threats. Theories of crime and empirical studies on user victimization as seen on social networks are reviewed. The chapter reflects on the role of social engineering as the entry point of many sophisticated attacks and highlights the relevance of the human element as the starting point of implementing cyber security programs in organizations as well as securing individual online behavior. There are numerous theories of crime that are relevant and applicable to cybercrime. However, this chapter focuses specifically on the routine activity theory (RAT) put forward by Cohen and Felson (1979) and the general theory of crime (GTC) introduced by Gottfredson and Hirschi (1990). These have relevance since the GTC is the most eminent latent trait theory of crime (Siegel, 2006) and the RAT gives a sociological explanation aimed at crime events rather than criminal propensities (Schaefer and Mazerolle, 2017), thus making both theories interesting and suitably applicable to cybercrime. This chapter also mentions the rational choice theory (RCT) as well as the deviant place theory (DPT) but to a lesser extent simply touches on some of the other existing theories of crime. For example, Cohen and Felson (1979) argue that crime will occur when there is a motivated offender, a suitable target/potential victim and the absence of guardians capable of preventing any violation. The latter can be in the form of physical guardianship (e.g. antivirus) or personal guardianship (e.g. computer skills). In addition, Gottfredson and Hirschi (1990) suggest that crime and victimization are associated with low levels of self-control. We then turn to empirical studies that have examined the user behavior on SNS leading to victimization (e.g. Hansen et al., 2017; Saridakis et al., 2016; Benson et al., 2015a-c). Issues associated with the emerging trends in human behavior research and ethics are presented for further discussion. The chapter concludes with a set of open research questions warranting immediate academic attention to avoid the exponential growth of future information breaches.

BACKGROUND: THEORIES OF CRIME

Research suggests that the frequency of internet usage shares a positive association with cyberbullying and victimization (Mesch, 2009). However, in modern times, most individuals, public organizations and private ones are heavily dependent on the usage of the internet to carry out their daily business activities and communications, therefore, limiting internet use is not a plausible solution to the problem of being

a victim of cybercrime. Thus, there is a need for examining the roots of the problem, which starts with people and the psychology behind human behavior that triggers cybercriminal activities. To this end, a number of theories have been developed to explain the psychology behind criminal activities. The RAT proposed by Cohen and Felson (1979), for example, suggests that crime is contingent on the following three components: exposure to a motivated offender, a suitable target and the lack or absence of capable guardians to prevent the violations. Furthermore, Cohen and Felson (1979) describe the suitability of a target as their attractiveness to the motivated offender as well as their availability for the crime. Therefore, if there is a situation where all three components of the RAT are present, then a crime is likely to occur.

According to Marcum et al. (2010), crime is not a random event, instead it follows a consistent pattern where the three components of the RAT are required. Eck and Clarke (2003) propose that the RAT can be expanded for cybercrimes where the offender and target do not necessarily share the same physical space but can share the same cyberspace such as the internet or any shared network.

In the context of cybercrime, the motivated offender is someone who is not only capable of committing the cybercrime but is also willing to commit it because he/she is motivated by personal gain such as identity theft, phishing, espionage, unfair investment information, bank fraud, someone's personal information or even revenge. The suitable target can be an individual or an organization who possesses the online information from which the motivated offender can gain. Finally, the guardian can be in the form of a software guardianship (e.g. antivirus or firewall), personal guardianship (e.g. computer skills or cybercrime awareness) and even physical guardianship such as a capable cybercrime unit or security personnel who can protect the parameters of an organization from intruders seeking to gain access to their network server.

Marcum et al. (2010) derive an explanation for the online victimization of youths (generation Z) using the RAT by suggesting that the great length of time spent on SNS increases their exposure to a motivated offender. Also, the types of information that they provide on these SNS (i.e., age, relationship status, daily activities, and pictures) make them suitable targets for online victimization. Furthermore, the insecure location in which the internet is being used by youths combined with their personal and parents' lack of expertise in cyber technology or internet security provides the third component of the RAT, which is the lack of capable guardianship.

While we reason that prior experience of online victimization by individuals on SNS increases their probability of noticing online security features and increasing their guardianship, a study by Benson et al. (2015b) finds otherwise. Benson et al. (2015b) find that there is no connection between these two factors and suggest that this can be explained through an individual's perception of the utility obtained from SNS for entertainment, socializing and other activities which is higher than the risk of online victimization to them.

Another major theory that is used to explain crime and victimization is the GTC, proposed by Gottfredson and Hirschi (1990) which suggests that the principal causal agent of all crimes and victimization is low self-control. There are six elements associated with low levels of self-control, which are: lack of future orientation, temper/anger, lack of diligence, self-centeredness, preference for risk taking and a preference for physical over mental tasks (Piquero et al., 2005). Individuals with low self-control are more likely to get angered easily than their counterparts who have high self-control and a similar statement can be made about each of the six elements associated with low self-control. According to Gottfredson and Hirschi (1990) there is a lot of shared personal and social characteristics between victims and offenders. Piquero et al. (2005) suggest that offenders of crimes are more likely to be victims of crime compared to non-offenders. The six elements of low self-control can be used to explain cybercrime offenders and cybercrime victimizations.

Individuals who demonstrate the first element, which is a lack future orientation, can influence victimization because they do not consider the long-term consequences of their actions neither do they take precautionary measures to protect the image of their online identities nor to protect their private and personal information from being stolen and shared on the internet. On the other hand, offenders of cybercrime demonstrate a lack of future orientation by failing to consider the illegality of the cybercrimes which they are committing and the long-term consequences if caught, which can possibly include jail sentences and permanent criminal records.

The second element, anger/temper, can result in individuals expressing these emotions on SNS which may include politics and other topics that can potentially elicit counter-controlling responses by other individuals who may be offended and thus respond through a cyber-bullying attack. Some cybercrimes such as cyber-bullying and cyber-harassment are as a result of offenders who hold anger for other individuals or firms and therefore seek revenge through cyberattacks.

The third element, lack of diligence, can increase victimization since an individual who lacks tenacity is less likely to take precautionary measures against cyberattacks such as the installation of an antivirus or firewall and the assurance that it is updated regularly.

Offenders who engage in cybercrimes such as phishing, espionage, bank fraud and the theft of personal information for financial gain exhibit a lack of diligence by choosing to commit cybercrime in order to generate income instead of a legal job. The fourth element, self-centeredness, relates to victimization. Since self-centered individuals are more likely to ignore the advice or request of others and show concern only for their own situation, this can create a lack of awareness of current cybercrime activities and preventative measures. Offenders demonstrate self-centeredness through their lack of care for their victims' emotional trauma or financial struggle that can arise from cybercrimes. The fifth element, preference for risk taking, increases victimization since individuals who are risk takers may visit more risky websites, purchase at untrusted retailers for lower prices and even skip security checks, thus increasing their probability of being attacked. Offenders of cybercrime are also risk takers since the act of committing these crimes exposes them to the consequential risk of being caught. The final element of low self-control can influence victimization since in non-cybercrimes we can argue that individuals who prefer physical tasks over mental ones are more likely to respond physically when faced with a hostile situation rather than use cognitive skills to arrive at a solution which is similar for offenders. This final element of low self-control is the only one that may not support cybercrime since the offenders of this must have the mental capacity required to commit such an act. According to Schreck (1999) vulnerability to victimization is a by-product of the psychological appearances of low self-control.

Another theory that describes the psychology of human behavioral influence on crime is known as the RCT. This theory explains that an offender will violate the law after rationally considering personal factors (i.e., the need for money, family, dependents, revenge, consequence and entertainment) and situational factors (i.e., how well the target is guarded and the competence of the local police service). Therefore, if an offender rationalizes that the consequential risk of the crime does not outweigh the reward gained from committing this crime, then the offender will commit the crime (Siegel, 2006). In the context of cybercrime, an offender will commit an act such as cyber-bullying, cyber-harassment, identity theft, espionage and even theft of personal and banking information if the satisfaction obtained through committing any of these cybercrimes is greater than the probability of getting caught by officials in addition to the dissatisfaction felt as a result of the consequences. The RCT can explain how the high number of cybercrimes worldwide, due to the low probability of being caught, may be because of a lack of efficiency, competence and training of local police officials in handling cybercrime incidents. There

exist very few studies which used the RCT to explain cybercrime activities, therefore more research is needed in this area.

Finally, there also exists the DPT that is used to explain victimization. According to this theory, individuals who have higher exposure to dangerous places have a higher probability of being a victim of a crime (Siegel, 2006). Therefore, this theory suggests that individuals should avoid dangerous places (e.g. crime hotspots) to lower their probability of being victimized. This theory can be expanded to include cyberspace and not just a physical space. Therefore, in the context of cybercrime, individuals who are exposed to dangerous cyberspace such as unsecure websites and unsecure internet networks, are more likely to be victims of a cybercrime. This theory is closely related to the RAT since the exposure to a dangerous place used in the DPT is similar to the concept of the convergence of the motivated offender and a suitable target used in the RAT.

FOCUS OF THE ARTICLE: LINKING CRIME THEORIES AND EMPIRICAL EVIDENCE

Cyber threats lead to two types of crimes (McAlaney et al., 2018) namely cyber-enabled and cyber-dependent crimes. On one hand, the internet technology is used to assist existing offences and such cyber-enabled crimes include e.g. fraud. The first vector of attacks is often established through the social media, where the offender researches the victims' profiles and/or gets in touch with them. Therefore social media serves as an assistive technology to cyber-enabled crimes. On the other hand, cyber-dependent crimes exist owing to the opportunities offered by the internet technology. Both hacking and malware distribution are examples of cyber-enabled crimes. These crimes are often perpetrated and spread via social platforms, thus making social network enablers of convergence of the motivated offender and a suitable target (Saridakis et al., 2016).

There are numerous studies worldwide that have adopted some of these theories of criminology to address the issues surrounding crime, and these theories have been expanded to be used in the analysis of cybercrime in recent times. One such example is a study by James et al. (2014) which suggests that older individuals are more likely to be targets for cybercrimes due to accumulated wealth, social unfamiliarity and trusting nature. This is consistent with the RAT since the older an individual is, the more suitable a target he/she becomes for a motivated offender due to the lack of guardianship. More young adults use the internet and more frequently than older adults, in fact 89% of young adults between the ages of 18-29 uses the internet for social media (Pew Research, 2015). This age group is very similar to the age group of university students. This group also manifests the preferences for conducting the commercial and business activities in purely online mode, making themselves the prime targets for criminal activities within cyberspace. A study by Benson et al. (2015c) finds that university students are less likely to be victims of cybercrimes as compared to non-university students. This can be explained using the Gottfredson and Hirschi (1990) GTC, since university students are generally more future oriented and thus have a higher level of self-control as compared to non-university students. Alternatively, this can also be explained using the RAT since internet servers used by universities are very secure and therefore increase the guardianship to prevent cybercrimes.

Research by Marcum et al. (2010) shows that a higher exposure to motivated offenders combined with allowing personal information to be accessible online, results in a higher probability of online victimization among college and high school students. Furthermore, a study done by Marcum et al. (2010) shows that communication with strangers online and provision of online contacts with personal or private

information are the most significant predictors of cyber victimization. This study is consistent with the RAT and since this activity merges the motivated offender with the suitable target, it is also consistent with the GTC as sharing of private information with strangers is a risky activity associated with lower levels of self-control. Also, it is consistent with the DPT since spending time on social networks with strangers increases your exposure to victimization in a dangerous place (cyberspace).

The RAT describes the importance of guardianship in the fight against crime and as a preventative measure against victimization. One form of guardianship in the context of cyberspace is security software. However, the UK Government's National Cyber Security Tracker revealed that only 44 percent of the internet users in the UK installed a security system such as an antivirus software, 37 percent updated these software regularly and furthermore, only 57 percent ensured that a website was secure before purchasing from that website (Home Office 2013, as cited in Williams, 2015). Williams (2015) finds that there is a negative relationship between software guardianship (e.g. antivirus and firewall) and identity theft victimization and his research quantifies this negative relationship by saying that a reduction in software guardianship by one point will result in an increase in identity theft victimization by 1.32 times. Additionally, a study on child online safety by Tennakoon et al. (2018) finds that self-employed parents are more likely to monitor their children's internet activities compared to parents who work in the private sector. Hill and Duncan (1987) suggest the "absent mother" hypothesis, which argues that when a mother works away from home it affects her child's behavior and development since her ability to supervise and socialize with her child is restricted and limited. McLanahan (1985) propose a similar explanation for absent fathers. Therefore, self-employed parents provide extra guardianship through monitoring of their children's internet usage, which explains the increased guardianship that would result in a lower risk of children being victims of cybercrimes, according to the RAT. Furthermore, Tennakoon et al. (2018) find that self-employed parents use online technology more frequently and are more aware of possible threats online such as cybercrimes, therefore this increases their capabilities as guardians to protect their children from cyberattacks.

Cybercrime includes identity theft and online banking information fraud. A study by Williams (2015) finds that individuals who sell goods online have a victimization rate that is 1.56 times higher than those who do not sell goods online. Another study by Pratt et al. (2010) finds that the routine of online shopping at online stores and spending time online are significant predictors of cybercrime. These two factors are more significant than the age and education of consumers. Therefore, it can be reasoned that the act of selling, auctioning or buying goods online is a risky routine activity that will increase the likelihood of being victimized in cyberspace, which is consistent with the theories discussed above.

Moreover, research shows that increased usage of SNS tends to increase the probability of convergence between motivated offenders and suitable victims in cyberspace (Reyns et al., 2011). Interestingly, however, Saridakis et al. (2016) find that individuals who have a higher usage of dominant multipurpose social media sites (e.g. Facebook and Google+) are less likely to be victims of cybercrimes. However, the study also finds that individuals who have higher usage of knowledge-sharing through social media (e.g. LinkedIn, Twitter and Blogger) are more likely to become victims of cybercrime. These findings could be explained through the psychology of human behavior since the public mindfulness of the inherent risk associated with dominant social media sites may cause them to take additional precautions compared to the perceived level of trust and safety associated with knowledge-sharing social media sites where they may take less precautionary or safety measures. Furthermore, Saridakis et al. (2016) show that higher computer skills and greater technological efficacy is positively but statistically insignificantly related to victimization. The researchers argue that the positive relationship could be due to the individual perception of their superior computer skills resulting in an increased risk-taking behavior that exposes them

to higher probabilities of victimization. This finding is consistent with Gottfredson and Hirschi's GTC since this can be viewed as a preference for risk-taking behavior, which is an element of low self-control, therefore this characteristic increases the individual likelihood of being victimized.

CONCLUSION

There are several theories outlined in this chapter, which include, the RAT, the GTC, the DPT and the RCT, all of which attempt to address the phenomenon of human behavior that leads us to commit an act of crime. The desired approach to crime should not be merely to catch the offenders of crime but to prevent the occurrence of a crime by addressing and removing the stimuli that encourage or allow it to happen. All these theories of crime have been modified and extended to include the new age of cyber-crime especially in the financial sector and among all individuals using SNS.

To gain better insights in addressing evolving challenges of the digital world, cybersecurity increasingly relies on advances in research done on human behavior. Whilst technology may often form the core of cyber-attacks, these incidents are instigated by and responded to by people. Researchers believe that SNS are important tools that promote social exchange since social interaction plays a vital role in education (Vollum, 2014, as cited in Benson, 2015c). Therefore, strategies should be developed to minimize the risk of cyberattacks which will allow the continued use of SNS to promote social interactions in a safer cyberspace. Researchers also need to address the issue of privacy since privacy on SNS is not only an individual issue but also an organizational and institutional one that involves data sharing actors (Benson et al., 2015a). The number of registered social network users and the amount of time spent on social network increase every year. In addition, the commercial value of personal information on SNS is on the rise (Benson et al., 2015a) having a tangible contribution to the digital economy. Therefore, with this growing rate of technology and increased dependence on the internet for SNS and other essential functions, our risk of losses due to cybercrime is continuously increasing.

Strategies to be used in the protection against cyberattacks can be intelligently developed and delivered by the government awareness programs, public places and on television to raise awareness of cybercrime. For example, a study by Marcum et al. (2010) suggests that youths lower their probability of online victimization by communicating only with people whom they know on SNS, and not giving personal information to people that they do not know. Furthermore, by gaining a better understanding of the human aspect of cybercrime through psychology, we can develop better mitigation strategies for cybercrimes. This area of human element exploration has a big impact on the future of computing. As such, the younger generation is driving the commercialization of social media platforms. Therefore, gaining a better understanding of their behavioral traits, intentions and acquisition of safe usage patterns are imperative for the prevention of criminal exploitation of the young user of SNS.

RESEARCH QUESTIONS OPEN FOR FURTHER DISCUSSION

This chapter ends with a series of questions warranting future research to explore. These include:

- Should strategies be adopted based on the target age group, as different age groups have different online skills and use the internet for different purposes?
- Do geographical location, technological literacy and culture play a role in determining the types of cybercrime activities?
- Does the risk of losses due to cybercrime activities outweigh the efficiency benefit of implementing the emergent digital technology offerings?
- Can a connection between suicide incidents, mental-illness, cyber-bullying or identity theft cases be established by researchers?
- Governments have placed significant emphasis on privacy regulation. Should they continue to regulate the privacy controls of SNS or leave it up to the owners of the SNS to prioritize data commercialization over individual privacy?

This is the time when academic attention is so valued, having the potential to mitigate future cyberattacks, as well as minimize their impact on individuals who are yet to realize their full potential in business and enter the workforce. In order to take control of online victimization, the relevant stakeholders, including policy makers and SNS vendors, need to have sufficient control and public awareness to support a safer online future for the younger generation.

KEY TERMS AND DEFINITIONS

5

Cyber Security: Cyber security is the protection of internet-connected systems, including hardware, software, and data from cyberattacks.

Cyber Security Skills: Cyber security skills are those skills associated with ensuring the security of information technology (IT-generally referring to information storage and integrity) and operational technology (OT-referring to systems that control physical devices).

Cyber-Victimization: Cyber-victimization refers to the process in which others are victimized through the use of information and communication technologies.

Cyberattack: A cyberattack is a malicious and deliberate attempt by an individual or organization to breach the information system of another individual or organization.

Cybercrime: A cybercrime is any criminal activity that involves a computer a networked device or a network.

Risky Online Behavior: A risky online behavior is an action that can potentially leave one exposed to a variety of dangers, putting individual and possibly organizational internet security at risk.

Social Network: A social network is an online communication platform that is used for creating relationships with other people who share an interest, background or real relationship.

Online Expression, Personal Cybersecurity Costs, and the Specter of Cybercrime

INTRODUCTION

The UN General Assembly has declared freedom of expression to be a universal human right (UN General Assembly, 1948). As of 2016, the United Nations has resolved that unrestricted access to the Internet is also a human right (UN Human Rights Council, 2016). A commonly accepted benefit of the Internet is that it serves as a platform for free expression. Importantly, political topics are also discussed as well as other topics without socially accepted *savoir faire*. However, there are potential consequences for users who make controversial or provocative expressions over the Internet from other users and organizations participating in or following the communication (Baroni, 2015; Cassidy, 2017; Jaschik, 2014). Such consequences may also be in the form of illegal doxing or hacking attacks by cybercriminals.

Users' concerns about such consequences may have an inhibiting effect on their Internet usage for free expression. This inhibiting effect may correlate with what users believe and how users behave concerning addressing security and privacy issues of their devices. The inhibiting effect may also correlate with users' attitude toward and perception of the time they spend addressing their devices' security and privacy issues. However, the association between online expression aspects and the perception of time consumption on security aspects is lacking in prior research. Users may be reluctant to express themselves online simply because anonymity costs too much time and effort. That is, the users may be aware of the importance and abundance of tools providing anonymity and may wish to express themselves online but decide that spending time on anonymity is just too much effort. Concern about such consequences may not only have an inhibiting effect on users' use of the Internet for expression but it may also correlate with their desire to purchase personal cybersecurity products and anonymizing services.

Another generally accepted beneficial use of the Internet is as a platform for commerce, which is continuously increasing (Emarketer.com, 2014). At the same time, spending by consumers and businesses on cybersecurity products and services is also increasing (Morgan, 2017). It is reasonable to expect that users purchase a significant proportion of personal cybersecurity software online. It is possible that misgivings of users about the Internet as a platform for free expression may correlate with increased Internet utilization by those same users for commerce in personal cybersecurity products and services. This article explores this somewhat paradoxical relationship given that the Internet is seen as an overall good for humanity. It leads to a focus of this chapter; that is, to the consideration of users' reluctance

DOI: 10.4018/978-1-5225-9715-5.ch067

to express themselves in relation to their attitudes and perceptions regarding the time and money they invest in security. This is relevant to participation in social media and other online expression contexts.

To facilitate research and discussion on this topic, six latent factors are elucidated: three corresponding to a reluctance to self-express online, one corresponding to a belief that handling security and privacy aspects of one's device requires an excessive amount ("too much") of one's time, and one for time considering device cybersecurity and privacy settings aspects. The sixth factor corresponds to a positive predilection toward personal spending to enhance personal cybersecurity. The correlation among two of these factors is then analyzed. A linear regression of one latent factor against the other and against a demographic factor is also performed.

This chapter presents an overview of related research, followed by a description of a proposed research model. It then establishes the general latent factors. Some results are presented and discussed, followed by a description of future research suggestions, and a conclusion.

BACKGROUND

Previous research has considered implications on free expression and the benefits of free expression. Willingness to express opinions online has been measured in terms of a web forum's view/reply ratio (Shen & Liang, 2015) and by asking users how likely they would be to express their opinions in specified online scenarios using a 0-100% or 0-10 scale (Ho & McLeod, 2008; Stoycheff, 2016). Hayes et al. (2005) established a self-reporting tool consisting of eight five-point Likert questions to measure willingness to self-censor. However, the tool's questions pertain to a general social context and not specifically to self-expression of controversial opinions on the Internet. Attempts to measure a reluctance to express on the Internet or to establish the same as a latent factor are lacking in previous research.

The emerging research of Booth (2017) has raised attention to the issue of freedom of expression and the laws and norms thereof in terms of their relationship to the benefits of ICT on national well-being. However, her research does not consider the relationship between the expression of free speech on aspects of the individual user. Internet communication is largely beyond the territorial control of the nation-state and access to the Internet has been recognized as important to the freedom of expression and to participation in a democracy (Lucchi, 2011). Previous research has established that usage of the Internet for free expression can be a way of circumventing censorship or other hindrances that prevent citizens' freedom of expression in more traditional publishing media, especially in authoritarian regimes (Nadi & Firth, 2004).

Prior research has shown that many states have begun imposing online surveillance upon their citizens by way of legislative acts or other means (Ray & Kaushik, 2017). The research suggests that the ostensible justifications for such surveillance, such as cyberterrorism or cybercrime, are questionable and disproportional to the scope of the surveillance desired by the state. Such surveillance does not directly restrict online expression but it can create hesitation or concern in the user. The user may hesitate to criticize the state or its policies in an online forum due to fear of being surveilled. Many states also impose varying levels of censorship and controls on online expression (Ray & Kaushik, 2017).

Debate and discussions that occur over online forums and social media, such as Twitter and Facebook, are raising the attention to a virtually unlimited array of topics. Importantly, socially controversial topics and political topics are also discussed. Certain organizations consider and evaluate the various threats to the freedom of expression online (Stanton, 2014). In oppressive states, free expression enabled by access to the Internet can be particularly important for advancing human rights (Nadi & Firth, 2004).

However, there are potential consequences for users who make controversial or provocative expressions on the Internet, including a negative reaction from the government (Baroni, 2015; Cooper, 2000; Mony, 2017) and offended individuals (Cassidy, 2017), employers (Jaschik, 2014), and schools (Curtom, 2014). Consequences may also be exacted by vindictive criminal hackers. Cybercrime against individuals has been defined as: “Offences that are committed against individuals or groups of individuals with a criminal motive to intentionally harm the reputation of the victim or cause physical or mental harm, or loss, to the victim directly or indirectly, using modern telecommunication networks such as Internet (networks including chat rooms, emails, notice boards and groups) and mobile phones (Bluetooth/SMS/MMS)” (Halder & Jaishankar, 2012). Victims may become a topic for cybercriminal gangs in the Deep Web or the target of doxing. “Revenge hacking” and doxing have caused serious consequences to victims (Branigan, 2011; Dascalescu, 2018). Participating in social media is a form of individual expression and there is some research-in-progress on the effects of perceived security threats on user’s social media behavior (Alqubaiti et al., 2016).

Users spend significant time performing self-protective cybersecurity and privacy-related tasks. This time detracts from the amount of time users have available for other preferred activities. For example, when using open WiFi connectivity in a public space or vehicle, spending time connecting to a secure VPN or updating the security software will leave less time for messaging and for checking social media updates. The excess use of time spent waiting can be merely a perception but may still have negative consequences in terms of user experience or perception of the services for which the waiting is done (Dellaert & Kahn, 1999). Another study has been performed to determine how consumers react when web pages of shopping websites take too much time to load (Anonymous, 2010). It found that 70% of respondents reported that they abandon shopping on a site if the site takes more than 10 seconds to load and 35% said they would not return if the loading delays take “too long.” On the other hand, the tolerance of users to the amount of time spent waiting will vary according to the individual and the context (Katz & Martin, 1989). During Internet usage, a loading delay may be experienced with most mouse-clicks or screen taps. However, the need to spend time waiting for a security software update process to complete occurs relatively infrequently, e.g. weekly or monthly.

Excessive non-ideal time consumption, therefore, can be said to detract from more desirable activities and may cause a negative perception of offerings associated with waiting. Frustration with excessive time consumption can result in a negative attitude toward, and possibly abandonment of, desirable online content and activities.

Controversial expression in an online communications context is affected by other factors. Such factors include perceived anonymity and familiarity with other online community participants (Luarn & Hsieh, 2014). Luarn and Hsieh studied the expression behavior of users in a laboratory-controlled virtual community. The virtual community simulated different online group communications environments. They found that users were more willing to express controversial opinions when their identities were anonymous or when they were familiar with other members of the community. When users in the study were not anonymous, they were more reluctant to express such opinions. They also found that there was no effect of anonymity or member familiarity on users’ willingness to express non-controversial opinions.

Prior research has shown that negative expressions are received differently than neutral or positive ones. Kwon et al. (2013) studied communications and expressions in a messaging context. They examined the acceptability of negative communications. They found that emotional expressions that accompany negative communications were considered much less acceptable than emotional expressions in positive ones. Negative messages by their nature are less welcome. Negative expressions (e.g., unpleasant or aggressive) can result in unwanted consequences. Internet users may be reluctant to express themselves

because of concerns about such consequences. The time they spend on personal cybersecurity issues may further discourage their controversial expressionism.

It is of note that Booth and other researchers utilize the Human Freedom Index (HFI) (Vasquez & Porcnik, 2017). Included in the HFI measures are those that measure freedom of expression. Among those measures are “Laws and Regulations that Influence Media Content,” “Political Pressures and Controls on Media Content,” and “State Control over Internet Access.” The measures of Laws and Regulations that Influence Media Content and Political Pressures and Controls on Media Content could be useful for this study on the condition that they are applied indirectly. That is to say, for example, that an assumption would be that an average user would feel some reluctance to freely express themselves as a result of the laws and controls. This study addresses reluctance more directly in the survey questions, whereas the subset of HFI measures does not measure reluctance to express. The HFI’s “expression freedom” measures have not been examined for their relationship to personal cybersecurity spending. In particular, they do not measure concern regarding the consequences of personal free expression and neither have they been analyzed for their relationship to Internet users’ attitudes and behaviors toward purchasing personal cybersecurity protections.

There are also studies observing the impact of demographic factors, such as nationality and age, on Internet behaviour that are relevant to this study. Regan, FitzGerald, and Balint (2013) have evaluated attitudes toward information privacy between age groups (specifically generations). Their analysis revealed a trend where younger generations tend to be more concerned than older ones about wiretapping and data privacy. Chen, Hsu, and Lin (2010) determined that consumers with different levels of computer expertise have different preferences for attributes of shopping websites. Research into culture-based differences in perception of risk for online shopping and other tasks has yielded conflicting results (Sims & Xu, 2012). Sims and Xu (2012) found no significant difference between the UK and Chinese shoppers’ perceived risk of online shopping despite those shoppers’ differing cultural backgrounds. This conclusion was against their expectations and the contradicted results from prior research that showed differences in risk-aversion between the two cultures (Hofstede, 1980).

Sheehan (2002) found that users’ education and age correlate with their level of concern about online privacy. Hazari and Brown (2013) studied whether demographic variables can affect Internet users’ privacy concerns and, thus, their attitudes toward using social networking sites. In contrast to the results from Sheehan and from Regan, Fitzgerald, and Balint, their research found that age was not correlated with online privacy concerns. Bandyopadhyay (2011) found that factors such as the level of Internet literacy, social awareness, and cultural background affect Internet users’ online privacy concerns. He found that among the possible consequences of such concerns is an unwillingness to use the Internet. Liu et al. (2016) applied social exchange theory to examine perceived risks and rewards of individual users’ self-disclosure in social media. The authors found that perceived privacy risk can reduce the willingness of social media users to disclose personal information. There does not seem to be existing research on social exchange theory applied to controversial expression by individual users online. Previous work has examined the effect on willingness to disclose information about oneself. Based on previous research, it can be hypothesized that the reluctance to express oneself on the Internet may be connected with concerns about the consequences. Further, reluctance to express oneself may lead to the use of cybersecurity as a means to protect oneself in these cases. However, there seems not to be previous results addressing this hypothesis.

Previous research has attempted to address the monetary and non-monetary costs of consumer-facing cybercrime (Riek & Böhme, 2018). The research focused on cybercrime incidents such as scams and payment fraud. The costs in Riek and Bohme's research are not the costs of the fear of consequences that could result from expressing oneself online. The feared consequences in the RtoEx subfactor of this study are unspecified and general. They may occur in varying forms including, but not limited to, cybercriminal attacks against the user.

The authors believe that it is important to consider the attitudes of users toward free expression on the Internet and possible consequences resulting from users' reluctance to freely express themselves on the Internet.

RESEARCH MODEL

This study proposes six latent factors: three corresponding to a reluctance to self-express online (RtoEx), one corresponding to a belief that handling security and privacy aspects of one's device requires an excessive amount of one's time (TMT, from "too much time"), and one corresponding to the performance of checking and changing device privacy and security settings (TChS, from "think about and change settings").

The factors are:

- **Reluctance to Express (RtoEx):** Reluctance to freely self-express online. The reluctance of expressing can be further divided into two factors based on inclusion or exclusion of consequences of the expression, RtoExC and RtoExnonC, respectively.
- **Reluctance to Express When Consequences Mentioned (RtoExC):** Reluctance to Express due to concerns of possible Consequences or safety; The reluctance to freely express oneself online due to concerns of possible consequences or safety issues resulting from the expression.
- **Reluctance to Express When Consequences Not Mentioned (RtoExnonC):** Reluctance to Express when users are not reminded of possible Consequences or safety issues resulting from the expression.
- **Too Much Time (TMT):** The belief that cybersecurity risk amelioration requires excessive usage of one's time
- **Think Change Settings (TChS):** Time considering two aspects of one's ICT device – contemplation of the device's cybersecurity aspects and whether the time is consumed specifically for the checking and possibly changing of device settings that relate to security and privacy.
- **Loss of Money (LoM):** Personal cybersecurity spending attitude and behavior; the willingness to buy software products or services that enhance personal cybersecurity.

As a demonstration, the authors hypothesize that those users who are conscientious about their online security and privacy will spend both time and money to ensure it. This should be reflected in a significant correlation between TChS and a positive attitude toward purchasing personal cybersecurity products and services (or LoM, for "Loss of Money")(Figure 1).

H1: TChS will be correlated with a positive attitude toward purchasing personal cybersecurity products and services (LoM).

H2: TChS combined with one or more demographic variables will predict LoM.

Figure 1. Latent variables TChS and LoM, and independent demographic variable(s)

Latent Factors and Their Indicators

Each of the latent variables can be derived from sets of indicator questions. Indicator questions for TChS and LoM were included in a survey, and each consisted of responses along a five-point Likert scale from “strongly agree” to “strongly disagree.” For data gathering, a survey was administered over the Web to a population composed mainly of Finnish university students and working adults. 191 responses were obtained.

The questions for TMT were as follows: five questions to assess the perception that excessive time has been spent addressing device security and privacy issues and a belief that time spent on device security and privacy aspects has detracted from time intended for other tasks. TChS is established with three questions to assess whether the user has contemplated and checked (and perhaps adjusted) their device’s security and privacy settings (available from the authors). Cumulatively, the authors suggest the five “too much time” indicator questions imply that the respondent spends time contemplating and actively addressing security and privacy aspects but tends to feel negative about doing so.

The survey included questions on respondents’ behaviors and attitudes regarding personal spending on cybersecurity. Latent variable Loss of Money (LoM) is defined by responses to a set of four indicator questions. The questions for LoM are designed as follows: two questions to ascertain whether the respondent/subject has purchased to enhance his cybersecurity and two questions to ascertain the general attitude of the respondent toward security software purchases (available from the authors). Cumulatively, it is suggested the LoM indicator questions indicate the willingness to buy software products or services that enhance personal cybersecurity.

An Exploratory Factor Analysis with direct oblimin rotation is used to extract latent components from a set of survey questions. The results for TMT, TChS, and LoM confirm three components. Review of the corresponding survey questions indicates that the TMT and TChS responses are differentiated by the mention of security issues detracting time from preferred tasks, or by a belief that addressing security issues takes too much of one’s time (Table 1).

A Spearman correlation analysis is performed on the indicator question responses corresponding to TMT (five questions), TChS (three questions), and LoM (four questions). All of the responses within the three respective sets of indicator questions have two-star Spearman correlations with each other (Table 1). Because the indicator questions for the three latent variables have high intercorrelation, the mean scores of the responses were computed and utilized for analysis. SPSS statistical software was used to calculate Pearson correlations between the latent variables as well as the Cronbach’s alphas. The Cronbach’s alpha values show acceptable reliability between the latent variables’ indicators (Table 1).

Table 1. Spearman correlations (two-tailed significance at 0.01 level) between indicator question responses for each latent factor; mean correlations; and Cronbach's alpha

Latent Factor	Minimum	Maximum	Mean	Cronbach's Alpha
TChS	.319**	.485**	.407	.673
TMT	.221**	.772**	.405	.766
LoM	.500**	.863**	.639	.871

Results for TChS and LoM

Analysis of the results (Table 2) for the TChS vs. LoM hypothesis shows a significant correlation, thus H1 is confirmed.

Regression analysis is performed on LoM as the dependent variable against some demographic variables. The analysis shows some correlation with the combination of TChS and age (adjusted R squared = .035, p-value = .013). H2 is therefore valid for age.

When the model is properly applied, hypotheses utilizing the other latent factors may be similarly evaluated.

SOLUTIONS AND RECOMMENDATIONS

From the viewpoint of encouraging open and robust political discourse, governments should ensure the framework and conditions for free expression by their citizens with online regulatory safeguards that correspond to the traditional safeguards in traditional communications media. This could help Internet users feel freer to spend money and time on personal interests instead of diverting spending due to concerns about their online privacy and security. If users would have less reason to be worried about becoming victims of cybercrime, they could spend more time expressing themselves and exploring offerings. In these ways, online merchants could benefit from more confident online consumers, and societies could benefit from the desired online discourse.

The HFI may be enhanced by the inclusion of a measure to assess citizens' reluctance to express legal, but controversial, viewpoints online. Citizens may be reluctant to express such viewpoints despite states' official policies allowing free expression. The concern about consequences resulting from such expression may not necessarily align with states' official policies and the possibility of state-imposed consequences does not necessarily align with states' official policies. The current HFI does not account for citizens' concerns and perceptions of these issues.

In the analysis, some differences between nationalities in the responses were noted. However, further data should be collected. One direction to search for a potential explanation is cultural differences (Hofstede, 1980).

Table 2. Pearson correlation between LoM and TChS. Two-tailed significance: * to 0.05 level

	n	Spend time thinking about and changing settings (TChS)
LoM	191	.160*

Better default security and privacy settings could reduce the perceived need for purchasing supplemental personal cybersecurity solutions. This would free up more time and money for users to apply to preferable tasks and transactions. Ideally, users should be confident that their devices have sufficient privacy and security protection “out of the box”. Prior research has shown that users’ trust in the safeguarding of their privacy and security is positively related to their online purchase intentions (Chen & Barnes, 2007).

FUTURE RESEARCH DIRECTIONS

Applied social exchange theory could be expanded to account for Internet users’ reluctance to freely express their thoughts and opinions online. Further research could explore the factors that inhibit users from expressing controversial viewpoints and factors that encourage such expression online.

The indicator questions used in the demonstration study did not examine how, in the case of waiting, the management of time affects the perspective of the person waiting. Examples of such cases could be the users’ management of the time spent waiting for a security software update to install; or the content displayed on screen by the software during the update (Hanyang, et al., 2015).

For the TChS vs LoM hypothesis, future research could examine the impact of attitudes toward, and usage of, free and open source personal cybersecurity solutions. Users who believe they can achieve acceptable levels of personal cybersecurity with free tools would not necessarily be purchasing such tools. This could affect the LoM factor and thus the significance of the correlation between LoM and TChS. Regression analysis showed that age affects the TChS vs LoM correlation. Younger users who take time to contemplate their device settings feel more positive about spending money on personal cybersecurity.

This demonstration study did not consider free and open source personal cybersecurity products and tools that are available. Such tools include Tor browser, ClamAV, and free VPN services. Some respondents may have responded negatively to the survey questions regarding spending because they believe that they can achieve sufficient personal cybersecurity without spending money doing so. Future studies could account for such products.

Using the proposed research model and introduced latent variables, research can be performed to determine the effects of some independent variables (e.g., income and ICT expertise) on the relationships between the latent variables. Research can explore the relationship of certain demographic variables to personal cybersecurity spending and to any reluctance to express oneself online. Users could also be surveyed to directly gauge their concern about being victimized by cybercriminals as a result of their expressions. Subject to available survey data, analysis for geographical region clustering and other clusterings could also be performed.

CONCLUSION

While sales of cybersecurity products and services are suitable for the cybersecurity industry, they also indicate the real cybersecurity concerns of Internet users. Many Internet users go online, but may then be reluctant to freely express themselves, spending their time and money to alleviate perceived cybersecurity risks from political vigilantes, cybercriminals, or other entities. This scenario is not the ideal or optimal use of the Internet by society. Future research can investigate methods to encourage free expression online and reduce the perceived risks of such free expression.

In this chapter, an overview of research pertaining to the chapter topic was presented, and a simple research model was proposed. Six latent factors were proposed; three corresponding to a reluctance to self-express online (RtoEx, RtoExC, and RtoExnonC); one corresponding to a belief that handling the security and privacy aspects of one's device requires an excessive amount of one's time, TMT; one for time considering device cybersecurity and privacy settings aspects, TChS; and one for personal cybersecurity spending, LoM. Based on the factor analysis of the responses to some indicator statements, TChS and LoM were established.

A study using two of the latent variable showed a significant correlation between TChS and LoM, thus hypothesis H1 is confirmed. The association transcended nationality. The correlation was significant only when the entire response set was analyzed. Analysis by nationality did not show a significant correlation for any of the three most prominent nationalities of survey respondents. Regression analysis showed that age and TChS are predictors of LoM. Hypothesis H2 is therefore confirmed for age. Younger users who are conscientious about their device privacy and security settings are more likely to spend money on personal security or feel more positively about doing so.

KEY TERMS AND DEFINITIONS

HFI: Human freedom index; a numerical measure of the personal and economic freedom available in a country. It is measured annually. The HFI is determined from an evaluation of over 70 different indicators for each measured country.

LoM: Loss of money; personal cybersecurity spending attitude and behavior; the willingness to buy software products or services that enhance personal cybersecurity.

RtoEx: Reluctance to express; the reluctance to freely express oneself online or on the internet.

RtoExC: Reluctance to express due to concerns of possible consequences or safety; the reluctance to freely express oneself online due to concerns of possible consequences or safety issues resulting from the expression.

RtoExnonC: Reluctance to express when users are not reminded of possible consequences or safety issues resulting from the expression.

Social Exchange Theory: A behavioral theory that seeks to explain the interaction between a person and another person or entity. Its fundamental proposition is that the interaction is influenced by the person's evaluation of the interaction's risks versus rewards.

TChS: Thinking about and changing settings; time considering two aspects of one's ICT device – contemplation of the device's cybersecurity aspects and whether time is consumed specifically for the checking and possibly changing of device settings that relate to security and privacy.

TMT: Too much time; the belief that cybersecurity risk amelioration requires excessive usage of one's time.

Leveraging on Digital Footprints to Identify Potential Security Threats: Insights From the Behavioural Sciences Perspective

Loo Seng Neo

Home Team Behavioural Sciences Centre, Ministry of Home Affairs, Singapore

INTRODUCTION

The growing pervasiveness of the internet has revolutionised how individuals communicate and interact with one another. Despite being an effective channel for communication, it has also been exploited by individuals with malicious intent – such as criminals, violent extremists – for the purposes of fundraising, recruitment, propaganda creation and dissemination, sharing of vital information, data mining, etc. With the ease of accessibility and cloak of anonymity, individuals with malicious intent have reorganised their operations online to exist and operate in social environments that may not agree with their activities.

Violent extremists of all affiliations have exploited this technological advancement to transform the way they operate on a historically unprecedented scale. As Weimann (2004) posited, “Islamists, Marxists, nationalists and separatists, racists and anarchists all find the internet alluring” (p. 3). The internet and the opportunity it offers, allow violent extremists to expand the functionalities of their propaganda efforts beyond that the boundaries of the traditional, mainstream media (Europol, 2014). Violent extremists are no longer dependent on traditional media outlets to disseminate their propaganda. For example, it offers the opportunity for violent extremists such as Al-Qaeda in Iraq leader, Abu Musab al-Zarqawi to shape their audience worldviews. Before al-Zarqawi began his online propaganda campaign, it is essential to note that he would have to kill large numbers of people in order to grab the attention of supporters and media (Conway, 2007). However, through the online disseminations of video-taped beheadings of foreign hostages such as Nicholas Berg, al-Zarqawi was able to achieve greater impact and media publicity albeit using fewer resources. The internet has provided him with a readymade audience to exert his influence and presence. The use of the internet by individuals with malicious intent such as violent extremists therefore demands the attention of law enforcement agencies across the world.

In fact, the continuous advancement in information and communications technology can be envisioned to have a dramatic impact on the way such persons of interest may operate. Some recent examples include the online expression of hate during the 2018 Sri Lanka Kandy Riots (Gan, Neo, Chin, & Khader, 2018); acts of insider threats such as WikiLeaks data breach by Bradley Manning (Savage, 2013); online recruitment of members by violent extremist groups (Neo, Dillon, & Khader, 2017); ransomware attacks like ‘WannaCry’ (Tan & Wang, 2017); spread of fake news during the U.S. 2016 Presidential Election (Chen, Tan, Goh, Ong, & Khader, 2018); online circulation of upskirting photos (Luo & Wang, 2018); acts of cyberattacks (Dillon, 2016); and use of spear phishing to gain illegal access to computer networks (Vishwanath, 2016).

As the world witnesses an upward trend of such crime and security concerns in the online sphere, it places additional ‘responsibility’ on intelligence and law enforcement agencies to respond with the appropriate technological interventions (Abdul Rahman, 2019). Because the internet has played an im-

DOI: 10.4018/978-1-5225-9715-5.ch068

perative role in the way malicious activities are being conducted, these security agencies are therefore compelled to transform the way they identify potential persons-of-interest, collect usable intelligence, and conduct threat assessments.

In that case, how can individuals with malicious intent be identified in advance? How are they using the internet and social media to further their nefarious deeds? These questions can be addressed by examining how open-source digital footprints (i.e., one's online behaviours on social media and internet) should be harnessed to better identify and assess potential security threats. It is within these digital footprints where a potential perpetrator's intention and warning signs may manifest (Augenstein, 2017; Neo et al., 2017), which in turn can be utilised to assess the threat they pose. This chapter will discuss how digital footprints can be leveraged to identify potential security threats, particularly for crime and security issues that will result in negative repercussion at the national level, such as acts of violent extremism and hate crimes.

IDENTIFYING INDIVIDUALS WITH MALICIOUS INTENT USING THEIR DIGITAL FOOTPRINTS

The ability to disseminate information instantaneously and globally at very low costs provides these individuals with great opportunities to further their nefarious deeds. For example, on 29 October 2013, a video was released by an individual claiming to represent Anonymous via YouTube. It was addressed to the government of Singapore; the person threatened to disrupt key infrastructure in Singapore in an attempt to protest against the government's online regulatory framework (Neo et al., 2013). In another illustration, the Islamic State of Iraq and Syria (ISIS) spokesperson, Abu Mohammed al-Adnani, issued a call for attack on the 'enemies' of ISIS in 2014 via ISIS' repertoire of online platforms (Goh, Tan, Neo, & Khader, 2017). This led to an increase in the number of lone-wolf attacks by followers of ISIS in many parts of the world (Tee, Neo, Chin, & Khader, 2018). It is essential to note that such attempts to reach out and gain attention amongst the population would not have been possible without the internet. The internet has provided these individuals with a readymade audience to exert their influence and presence.

The use of information and communications technology inevitably leave behind publicly accessible digital footprints for intelligence and law enforcement agencies to follow. Personal information and stories (e.g., online expressions of personal sentiment, photographs of local places and happenings, geo-tagging a post, publicised social networks) are becoming easily available on websites and social media platforms (Whitty, Doodson, Creese, & Hodges, 2017). These changes in the access to digital footprints might be particularly useful for law enforcement and intelligence agencies who are increasingly drawing from online sources to assist in identifying potential security threats.

While this repertoire of open-source, highly personal and detailed cyber information can serve as leads for more technical means of intelligence gathering, the massive amount of these open-source digital footprints requires security agencies to be able to prioritise and focus their limited resources in their intelligence gathering endeavour (Skillicorn, 2009). There is also the need to ensure that the data points are reliable and credible. In the context of violent extremism, for instance, law enforcement agencies have utilised social media postings to incriminate individuals who are being radicalised online. In one case, Bilal Abood was arrested in Texas as a result of his Twitter activities. He used his Twitter account to pledge 'obedience' to ISIS leader, Abu Bakr al-Baghdadi, and had plans to travel to Syria to fight against the government of Bashar al-Assad. Although Abood originally denied that he had made the

Table 1. Eight warning behaviours

Warning Behaviours	Description
Pathway	Indication of research, planning and preparation of an attack
Fixation	Increasing preoccupation with person or cause
Identification	Identify with law enforcement, military paraphernalia, attackers or assassin
Novel aggression	Act of violence committed (unrelated to target) for the first time
Energy burst	Increase in frequency/variety of behaviours related to target
Leakage	Communication to a third party of an intent to do harm to the target
Last resort	Behavioural or verbal evidence of increasing desperation and distress
Directly communicated	Communication of a direct threat to target/law enforcement

pledge of allegiance to al-Baghdadi and ISIS, the particular post which identified this undertaking had in fact been ‘re-tweeted by others’ (United States of America v. Bilal Abood, 2015).

Consequently, the idea of leveraging digital footprints to detect potential security concerns is premised on the concept of assessing one’s online characteristics and attributes, to identify and decipher individuals with malicious intention. This may aid security agencies in identifying individuals who are at risk of orchestrating violent extremist attack, cyber-attacks, as well as hate crimes. The effectiveness of leveraging digital footprints, however, would require more than just its physical implementation of software and hardware (e.g., creating algorithms to identify relevant information) to support current operational practices. Besides understanding the mind and behaviour of the perpetrators, there is also about predicting and managing the identifiable behaviour effectively (Khader, Neo, Tan, Cheong, & Chin, 2019). As Khader (2011, pp. 5–6) opined, “behavioural sciences have much to say that should inform strategies for counterterrorism and counter-intelligence ... officers need to be constantly ahead of these behavioural trends by understanding through research the psyche of individuals, groups and trends”. The appreciation of how the field of behavioural sciences can act as force multipliers to understand perpetrators’ behaviours and cognitions will give us greater confidence on the steps that are required to search and identify potential security concerns in advance.

This chapter henceforth proposes the utilisation of insights from the behavioural sciences perspective to buttress the use of digital footprints: (i) identifying online warning signs; (ii) deciphering beliefs and motivations from social media data; and (iii) exploring the role of the online community.

Identifying Online Warning Behaviours to Targeted Violence

In the field of threat assessment, researchers have argued that there is always a pathway to targeted violence, with a series of perceptible thoughts and actions manifesting at each stage of the pathway (Borum, Fein, Vossekuil, & Berglund, 1999; Chai, 2019). The perpetrator’s actions would be influenced by a unique combination of precipitating characteristics and motivations over a period of time. To identify these perpetrators in advance, researchers have identified eight types of warning behaviours in the preceding days and weeks before they carry out their plans (Meloy, Hoffmann, Guldemann, & James, 2012; Meloy, Roshdi, Glaz-Ocik, & Hoffmann, 2015). Table 1 describes these eight warning behaviours by Meloy and colleagues (2012).

These warning behaviours are changes in behaviours that indicate an enhanced risk of violence which requires the relevant authorities to step in (Chai, 2019; Neo, 2018). However, the endeavour of assessing potential security threats is only possible if these warning behaviours are observed in the first place (Unsgaard & Meloy, 2011). Intelligence and information gathering are therefore crucial in detecting these warning behaviours. Extant research appears to suggest that out of these eight warning behaviours, some of them can be identified in the cyber realm. For instance, the warning behaviours of ‘leakage’, ‘fixation’, and ‘identification’ have been identified by Cohen and colleagues (2014) as having the highest likelihood of being exhibited by violent extremists in their online interactions within the group and their followers.

Leakage Warning Behaviours

Leakage warning behaviours refer to any expression of an intention to commit violent acts to a third party. Such online exchanges usually contain words that signal intent together with words that infer a preoccupation with the use of violence. This was seen in the ‘Unite the right’ rally by far-right followers, who are deemed as hate crimes perpetrators (Sheffield, 2017). On August 12, 2017, many far-right groups gathered to protest against the removal of the statue of a confederate general, Robert E. Lee in Charlottesville, Virginia. Violence broke out during the rally, resulting in three deaths. While attention has been focused on the violence perpetrated in the real-world, it is important to understand how these far-right groups used the internet to organise this rally. Based on leaked screenshot of chats from the app, Discord, these digital footprints showed participants planning for violence, expressing hatred and coordinating event logistics before the rally (Tiku, 2017). Through the leaked Discord chats, it was found that the perpetrators disguised a GoFundMe Campaign to raise funds for people to travel to Charlottesville so that they could attend the rally (Lecher, 2017).

Before conducting the 2019 Christchurch Mosque shootings, the perpetrator, Brenton Tarrant had posted on 8chan (i.e., an anonymous message board which allowed users to post radical right-wing thought) about his intentions to conduct an attack: “Well lads, it’s time to stop shitposting and time to make a real life effort post. I will carry out and attack against the invaders, and will even live stream the attack via facebook. The facebook link is below, by the time you read this I should be going live” (Resilience, Safety, and Security Psychology Branch, 2019, p. 3). Tarrant used Facebook to declare that he would be doing a live-stream video, and published his 74-page manifesto (Wakefield, 2019). The manifesto was sent to 30 New Zealand parliamentary email addresses (which included New Zealand Prime Minister Jacinda Ardern), and uploaded on social media nine minutes before the attack took place (Chavez & Holcombe, 2019).

Fixation Warning Behaviours

Fixation warning behaviours refer to any expression which signals an increasing pathological preoccupation with an ideology or person who is considered responsible for the individual’s grievance. For the former, some online users may express an ‘allegiance’, via their likes and associations, to a political party or radical movement that is deemed as sympathetic to their cause (Lucas & Aly, 2015). In the case of ISIS foreign fighters, they have publicly displayed their allegiance to the group, “We are no longer The islamic state of iraq and sham. We are only the ‘ISLAMIC STATE’. It’s official khilafa is restored! [sic]” (cited in Neo, 2018). For the latter, ISIS foreign fighters have demonstrated a strong preoccupation with groups that they deemed are responsible for the injustice faced by Muslims, “What treaty?? Didn’t America invade our lands rape our women torture us and kill our children, what treaty are u talking

about [sic]” (cited in Neo, 2018). There is an increasingly negative characterisation (e.g., anger, hatred) about the object of fixation in their digital footprints.

Identification Warning Behaviours

Identification warning behaviours refer to any narcissistic and grandiose online descriptions that indicate a desire to be a saviour or hero. The online users may espouse a warrior mentality, closely associate with weapons, and identify with a radical role model, group or radical action. Sympathisers and members of violent extremist groups often express an identification with radical leaders (military, ideological) or figures that are well known to be influential in any violent extremist groups or movements (Neo, Dillon, & Tan, 2016; Singh, 2011). For example, the social media pages of Anjem Choudhury, Musa Cerantonio, Ahmad Musa Jibril, and Anwar Al-Awlaki were some of the most common pages amongst ISIS supporters (Carter, Maher, & Neumann, 2014).

The capability to detect these three types of warning behaviours from one’s digital footprints—that are indicative of their intentions, ideology, and tactics—can serve as clues for intelligence and law enforcement agencies when conducting intelligence probes. This information is critical in aiding security agencies to identify and assess individuals who are potential security threats. More importantly, there is also some utility in carrying out further research to examine how these warning behaviours can be extrapolated to other online-related security threats.

Deciphering Beliefs and Motivations From Social Media Data

Information found on social media sites has become a valuable source of open-source data that could assist in the authentication and identification of an individual (Back et al., 2010; Whitty et al., 2017). A number of studies have attempted to use these digital footprints to predict an individual’s personality attributes—i.e., beliefs, motivations—, online behaviours, and feelings (e.g., Golbeck, Robles, & Turner, 2011; Quercia, Kosinski, Stillwell, & Crowcroft, 2011). For example, social media postings have been used to decipher an individual’s preferences for musical genres (Nave et al., 2018), employers’ hiring decisions (Newness, Steinert, & Viswesvaran, 2012), and likelihood of an individual having antisocial personality traits (Sumner, Byers, Boochever, & Park, 2012). A highly influential study by Kosinskia, Stillwell, and Graepel (2013) suggested that social media analysis can also offer a window into a broad range of characteristics including propensity for recreational drug use, status of parents’ marriage, preference for certain sports and teams, and political and religious views.

Recognising how online generated content by social media users may advance a deeper understanding of their beliefs and motivations, it can also be used to profile those that are of potential security concerns (e.g., radical worldviews, motivated by grievances). Such information could then be channelled towards the identification of relevant data point for intelligence and information-gathering. Within the field of online radicalisation, Edwards and Gribbon (2013, p. 45) argued that “[radical views] depends on the individual consumer in question ... while the internet might make information easier to find, ultimately the effect on the individual and their subsequent decision to take action will be a personal one”. In other words, what is of interest is how an individual’s characteristics (i.e., beliefs, motivation) can be used to assess an individual’s likelihood of becoming involved in violent extremism online. There is value to focus on personality dimensions like beliefs, motivations, as well as behaviours, where social media postings could be collected for data mining analyses to profile individuals of concerns in real time. For example, a set of personality, psycho-social and protective factors was identified by Neo (2018)

to detect individuals who might be involved in violent extremism online. In particular, six personality factors of interest were derived: perceived grievances; intolerance towards multi-religious, multi-racial living; knowledge to commit violent extremist offences; redemption and the pursuit for significance; susceptible to influence; and readiness to use violence. The author further validated these factors by comparing ISIS foreign fighters with ISIS sympathisers based on their social media postings on Twitter. It was revealed that the factor 'readiness to use violence' can be used to distinguish the foreign fighters from the sympathisers (Neo, Khader, & Pang, 2017). Beliefs as well as motivations of concern could be discerned from social media data by intelligence and law enforcement agencies when conducting intelligence probes. Furthermore, there is value to conduct further research to examine how other types online-related security threats could be informed by personality insights derived from social media data. However, the recent Cambridge Analytica scandal forces researchers and practitioners alike to reconsider the ethical concerns of harvesting personal data from social media users (Watkin, 2019).

Exploring the Role of the Online Community

While it is tempting to focus on the role played by personality-related factors and their functionality as predictors for online security threats, Pang (2016, p. 110) argues that "a practitioner who is seeking to use personality research to predict behavioural outcomes would not only need to know the type of behaviour a personality trait predicts, but also the specific environmental condition that is most likely to cause the behaviour to manifest". Since cyber-environments evolve more rapidly than physical environments, it is particularly important to contextualise the interaction of the individual, his/her current circumstances, and the influence of the online community to the process of identifying potential security threats.

Different threat actors would ascribe different meaning to their online behaviours based on these interactions. The internet has been exploited by violent extremists to create social milieus and subculture that cultivate partisanships and a community of like-minded individuals. This notion of an online community has been underscored by Bowman-Grieve (2009) when she observed that members in 'Stormfront', a radical right-wing forum, perceived themselves as part of a global community united by ties of solidarity that transcends geographical boundaries. For Tarrant, the Christchurch shooter, his online manifesto was able to inspire John Earnest to carry out a shooting in a synagogue in San Diego, Patrick Crusius to kill 21 people in a WalMart in El Paso, and Philip Manshaus to carry out a shooting in a mosque in Norway (Burke, 2019). While there was no evidence of direct cooperation between these attackers, there is a sense that they each feed off the other's narrative (Ward, 2019). Two of the attackers explicitly mentioned that Tarrant was a catalyst for their actions. They copied each other's ideas and formed a loose format for their atrocities, incorporating online manifestos, livestreams and memes from dark internet culture (Dearden, 2019). According to experts, members of these large right-wing online networks inspire and challenge each other to beat each other's body counts (Ward, 2019).

Furthermore, Hussain and Saltman (2014) suggest that the online violent extremist community can act as a replacement for the social environments that the members may lack in the real world. In this context, the internet does not only serve as an effective tool of communication, but also as an indirect medium to garner support and influence adherents' socialisation towards involvement in violent extremism. The endorsement of the radical ideology espoused by the online community may provide the 'push' factor that increases the likelihood of an individual to act in line with the ideology (Neo et al., 2017). It is within these online social interactions where an individual's motivation, intentions, and behaviours may ignite, and in the process, become potential security threats. Even in cases of lone-wolf attacks, these

perpetrators rarely become radicalised in complete isolation as they usually would have had engaged in some form of interactions with others in the online communities (Cohen, 2012).

It also suggests that it is important to focus not just on analysing the online violent extremist content, but also exploring how individuals use the internet to support violent extremist groups or movements. The structure and composition of an individual's online community may influence the course of action he/she might take (Ackland, 2013; Bartlett & Miller, 2013).

Using Social Media Analytics to Examine the Influence of the Online Community

Progress to identify potential online security threats can be made by understanding the online communities (e.g., social media platforms, websites, forums) and the dynamics within them. In her review of social media analytics, Yang (2016) described how tools can be developed to (i) map and measure the online social network, (ii) analyse online sentiment to identify which social media accounts to monitor, and (iii) examine the strength of relationships within the online communities. The outcomes of such analyses can help intelligence and law enforcement agencies explain the relationship between individuals (e.g., who is in their friend list, what is their membership status, their level of activity in the online community), and possibly predict behaviour resulting from these ties and even forecast potential security concerns. These online social networks may be explicit (i.e., memberships are formalised such as Facebook communities) or implicit (i.e., memberships are inferred based on online behaviours such as likes, comments, and links) in nature (Bartlett & Miller, 2013). These insights can then serve as a basis for understanding how close each individual is to the other individuals. For instance, social media analytics have been used to intervene in violent extremist financing networks, map networks of violent extremist organisations, and discover the role of each member of the online community (Barabási, 2012).

Researchers have attempted to utilise behavioural sciences and computational informatics methods to trace individuals with high risk of being radicalised by measuring 'signs and characteristics' from their interactions in online social networks (RiskTrack software tool; Camacho, Gilpérez-López, Gonzalez-Pardo, Ortigosa, & Urruela, 2016). The advantages of such a system is that it could guide the collection of digital footprints to track individuals of interest in real-time. Insights gleaned from the role of the online community can serve as valuable data points appropriate for cyber threat assessment. Future areas of research can focus on the manner in which other types of cyber actors with malicious intent may congregate online and influence one another.

SOLUTIONS AND RECOMMENDATIONS

In the current digital age, an assessment of security threats cannot be determined without looking at social media and online activity. These digital footprints offer intelligence and law enforcement agencies an alternative source of rich and potentially useful data (Antonius & Rich, 2013). Given that intelligence and law enforcement agencies have finite investigative resources (Skillicorn, 2009), the ability to analyse digital footprints would be crucial to better our understanding of online behaviour—particularly for crime and security issues such as violent extremism and hate crimes.

Solely depending on technological advancement to identify potential online security threats, would be insufficient in the long run (Yang, 2016). Amidst an increasingly complex operating landscape, it is essential to recognise how insights from a behavioural sciences perspective can enhance existing avail-

able measures or guide the development of new cyber-focused approaches. Hence, this chapter examines how three areas of behavioural sciences research (i.e., identifying online warning signs; deciphering beliefs and motivations from social media footprints; exploring the role of the online community) can help intelligence and law enforcement agencies who are seeking to leverage on the advantages of digital footprints to better identify online potential security threats.

Several implications for intelligence and law enforcement agencies are proposed. Firstly, to develop cyber threat assessment tools to complement offline information gathering. Some initial efforts can be seen in the development of CYBERA (see Pressman & Ivan, 2016), which analyses and assesses individual cyber-behaviour in support of violent extremism. The use of digital footprints to assess for threat also means that intelligence and law enforcement officers would have to be trained in new analytical skillsets so that the curated digital data can be properly analysed (Abdul Rahman, 2019). Related assessment tools can also be developed to analyse other types of cyber-related concerns such as insider threats, hate crimes, espionage, etc.

Secondly, to develop automated screening tools to detect individuals of concern based on their digital footprints. One of the most obvious implication arising from the discussion on the three areas of research is the manner in which a multidisciplinary approach (e.g., incorporating computational informatics methodology with insights from the behavioural sciences perspective) can be adopted to identify individuals with malicious intent. For example, behavioural sciences researchers can collaborate with computer scientists to employ machine learning (ML) and Natural Language Processing (NLP) technology to identify radical content on the internet. For instance, Gaydhani, Doma, Kendre, and Bhagwat (2018) used ML to automatically classify tweets on Twitter into three classes: hateful, offensive, and clean. The authors achieved an accuracy rate of 95.6 percent upon evaluating it on test data. Similarly, other researchers such as Biere (2018), have attempted to use principles of NLP to extract meaning from online postings and decipher their sentiments, in order to detect hate speech. Such techniques are especially useful given the large amount of data that is being uploaded onto the internet.

Thirdly, to work with social media companies to ‘adjust’ their recommendation algorithm with regards to radical content. Durkee (2019) reported that YouTube has modified its recommendation algorithm to limit recommendations of ‘borderline content and harmful misinformation’ that doesn’t violate YouTube’s rules outright. This ensures that the influence and outreach of such hate rhetoric are reduced. Further collaboration with social media companies should include the removal of radical content disseminated by individuals of concern, or remove or block social media accounts and websites that are perpetuating the radical ideology. However, it is important to note that ‘take down’ of radical content does not remove the perpetrators, it merely ‘displaces’ them and they may turn to other online platforms to disseminate their radical rhetoric.

Fourthly, to appreciate how the insights identified in this chapter could be utilised to guide the development of evidence-based research for various types of cyber threats such as scams, hacking, etc. Currently, this chapter largely focuses on how digital footprints can be leveraged to identify individuals who may endorse and engage in violent extremism. Thus, learning lessons can be extrapolated to help determine the types of data and information that are most useful for developing usable intelligence to prevent other types of cyber threats from materialising.

Fifthly, to identify the ‘right questions’ to guide the process of searching for relevant and useful digital footprints. Some challenges faced by security agencies may include: (i) the ambiguity in the meaning of the online behaviours attributed to the threats faced—they can vary from person to person; and (ii) the reliability and availability of data—it depends on the actions and choices of the users, social networking firms, as well as privacy regulations. In the event that a ‘wrong question’ is identified, it may lead

security agencies to overlook certain signals and focus their resources on data that form misleading or flawed assumptions about their person-of-interest.

Next, to advance the field of threat assessment in the local context. Whilst this might sound like a common-sense solution, there are not many local-based studies on cyber threat assessment. Notably, much of the emerging research on threat assessment (e.g., Meloy et al., 2012) were carried out in Western countries based on Western samples. Much more is still needed to address this paucity of local research, and ‘grow’ this business of threat assessment for online related security concerns. One difficulty of doing this kind of work well is that it requires a multidisciplinary approach. It requires a blended expertise on behavioural sciences (e.g., psychology, sociology, cultural studies, communication sciences), information and communications technology (e.g., machine learning, neural networks), and the use of empirical primary data to validate the process of threat assessment. Thus, some possibilities for future research questions include: (i) can threat assessment be done for other local cyber-related threats besides violent extremism? (ii) can insights from law enforcement databases be used to guide the research on threat assessment? and (iii) how can researchers better understand the interaction between personality characteristics of the individual and the online environment for these local cyber-related threats?

Lastly, it is important to introduce interventions that can directly mitigate the threat posed by individuals who have malicious intention. The act of assessment is not sufficient if there are no follow-up initiatives. In the content of combating online hate speech, efforts can be made to train community leaders and counsellors to engage with individuals of concern online about their hate rhetoric. This is to empower them with the knowledge and communication techniques so that they may engage those responsible for propagating hate speech. For example, as part of the ‘No Hate Speech Movement’, the Council of Europe conducted a series of training for young people to build their competences to combat hate speech on and offline (Council of Europe, 2016). Similarly, recognising the key role that the community can play in fighting hate and standing up to promote tolerance and inclusion, the Southern poverty Law Center (2017) has identified ten principles that members of the community can adopt to fight hate: (i) act; (ii) join force; (iii) support the victims; (iv) speak up; (v) educate yourself; (vi) create an alternative; (vii) pressure leaders; (viii) stay engaged; (ix) teach acceptance; and (x) dig deeper.

To conclude, the three areas of behavioural sciences research highlighted in this chapter may provide a basis for future research in helping intelligence and law enforcement agencies identify and predict potential security threats.

KEY TERMS AND DEFINITIONS

Identification Warning Signs: Signs that showcase evidence of identifying with law enforcement, military paraphernalia, attackers, or assassin.

Leakage Warning Signs: Signs that showcase evidence of communication to a third party of an intent to do harm to the target.

Online Communication: Any kind of communication between either individuals or organisations that occurs on the internet.

Threat Assessment: Threat assessment is a structured group process used to evaluate the risk posed by a student or another person, typically as a response to an actual or perceived threat or concerning behaviour.

Violent Extremism: A willingness to use or support the use of violence to further particular beliefs, including those of a political, social, or ideological nature. This may include acts of terrorism.

Warning Signs: Warning signs are acts which constitute evidence of increasing or accelerating risk.

Investigating Cybercrime in Nigeria

Mufutau Temitayo Lamidi

University of Ibadan, Nigeria

INTRODUCTION

Information communication technology (ICT) is a means by which relevant online information is managed effectively to achieve desired results. It involves the use of various electronic gadgets such as computers (desktop and laptop), tablets, iPad and other phone types as tools to access, manage or handle different forms of information on the Internet and derive from it the advantages it offers. Given the several advantages of ICT to national development, Nigeria, among other countries, has keyed in into it to partake of the benefits ICT offers. With a population of 186,987,563, Nigeria's Internet penetration is estimated to be 52.02% (African Union Commission & Symantec, 2016: 81). The Internet is gaining popularity by the day as it gains adherents with more people using it for their various needs. However, the advances in ICT have been both a blessing and a curse to Nigerians. It has improved people's lives in different areas, ranging from information dissemination to social networking, advertising, marketing, Internet banking and money transfer, among others. It has made conducting businesses by some professionals, especially in banking and finance, journalism and entertainment sectors, more effective. Particularly, it has enhanced government's cashless policy, which discourages citizens from carrying huge cash around town whether for business transactions or to purchase commodities in markets. Despite its several advantages, it also has disadvantages, principally, in cyber-attacks. Nwogwugwu & Uzoechina (2015) observe that although crimes (especially economic crimes) predated globalization, globalization and ICT that have promoted Nigeria's economy globally have become useful tools in the hands of economic offenders to commit crimes and launder proceeds of their illicit acts.

Reports are rife in newspapers, online forums and blogs about incidents of cyber-attack in Nigeria. This study investigates different cyber-attacks which are usually subtle and felt largely by the generality of Nigerians. The aim is to examine its nature in order to offer advice towards stemming its tide.

BACKGROUND

Cybercrime is described as "crimes committed on the internet using the computer as either a tool or a targeted victim." (Kamini, 2011: 240). The computer is a tool when it is used against a victim such as in theft, pornography and online gambling; and the computer is a target when its programme, software or structure is deliberately destroyed/vandalised.

Cybercrime can be targeted at organisations, individuals or the society at large. For organisations, governments, firms, companies or groups of individuals are usually targets. In this wise, there is unauthorised access to/control of computer system, possession of unauthorised information, cyber terrorism against government organisation and distribution of pirated software (Kamini, 2011). For instance, Symantec (2016: 81-82) reports that Nigeria has faced a daily increasing challenge in vulnerability User Datagram Protocols, UDP, up to 25%; botnet drones, 20%; web defacement of government websites, 3%

DOI: 10.4018/978-1-5225-9715-5.ch069

increase, weekly average; and phishing, 4% daily average. Hence, it is no surprise that Nigeria has ranked third in four consecutive years (2006, 2007, 2008 and 2009) on the list of world cybercrime perpetrator countries (Dagaci et al., 2014).

For individuals, their person or property is the target. Individuals often get harassed through e-mail, cyber stalking, dissemination of obscene materials, defamation, indecent exposure, e-mail spoofing, cheating and fraud. Their properties may be vandalised, viruses may be introduced into their systems, and there may also be intellectual property thefts, Netrespass Internet time theft and unauthorised control/access over their computer systems.

For the society at large, cybercriminals target anyone and everyone indiscriminately. In this category are cybercrimes such as (child) pornography, polluting the youth through indecent exposure, trafficking, financial crimes, sale of illegal articles, online gambling and forgery.

Cybercrime has been studied from different perspectives. Studies such as Ayofe and Osunade (2009) and Dagaci et al. (2014) view Cybercrime from a generalist point of view. Kamini (2011) and Toyo (2017) actually investigated it as a phenomenon, especially in their country or state of abode, and Aribake (2015) and Ojeka et al. (2017) studied it from a professional angle. In addition, while Okeshola & Adeta (2013) and Omodunbi et al. (2016) studied cybercrime from a sociological perspective, Nwogwugwu & Uzoechina (2015) looked at it from an economic perspective, Chawki (2009) from a legal perspective, and Boniface & Michael (2014) from a technological perspective.

Against the backdrop of Nigeria being ranked third on the list of world cybercrime perpetrator countries for four consecutive years, Dagaci et al. (2014) examine the major causes, forms, rate of victim, economic cost to Nigeria and alternative strategies of reducing the menace. Ayofe and Osunade (2009) also define the concept of cybercrime and identify reasons for it, how it can be eradicated, those involved and the reasons for involvement. They suggest how to detect criminal mails and proffer solutions to checking the increasing rate of cybercrimes and criminals.

Kamini (2011) is one of the studies that examine the effect of cybercrime in India. It discusses the types of cybercrime, the mode and manner of its application as well as the legal frame operating against cybercrime in India. It finally suggests what individuals and corporate bodies can do to prevent cyber-attack. Another study is Toyo (2017), which focuses on Abraka in Delta State of Nigeria. The study examines the causes and types of cybercrime prevalent in Abraka, the players and the impact on the society. It identifies causes of cybercrimes as urbanisation, quest for wealth, weak implementation of cybercrime laws and ill-equipped security agencies as well as negative role models. It observes that yahoo attack and hacking are the most prominent cybercrimes in Abraka; and cyber-attacks often result in financial losses, mistrust of youths, carnal abuse and government's abandonment of rural communities. It suggests some control measures like establishment of national institutions, awareness and training, upholding ethical and moral standards, using computer forensics and anti-virus, and establishment of laws to control the menace.

Okeshola & Adeta (2013) and Omodunbi et al. (2016) also discuss cybercrime from the perspective of education and society. The researchers drew data from tertiary institutions in Zaria and Ekiti State. They identified different reasons why cybercrime thrives and proffered suggestions to curb its menace. They noted that youths, especially males, are the major players in cybercrime. Okeshola & Adeta, for instance, identified some of the motivational factors as

...money/ financial gain, recognition/fame, low rate of conviction or even being caught, easy to perpetrate, intellectual pursuit, frustration, revenge, display of wealth by corrupt politicians and yahoo yahoo boys, laziness, un satisfaction(sic) from what they earn, lack of good moral upbringing from parents and guardians (p. 110).

Another researcher, Chawki (2009), discusses the laws guiding the crime of Advance Free Fraud as well as how effective it is in the context of cybercrime. The study suggests that the laws against cybercrime be strengthened and security officers and legislature be trained in the application of laws to arrest the menace. Boniface & Michael (2014) on the other hand suggest that Internet technology be improved such that each internet user will be identifiable through their identification details which must have been pre-registered prior to their use of the Internet.

These studies provide a background for the current paper. Being a developing country that is still struggling to combat Cybercrime, Nigeria may compare notes with India, given the author's submissions as regards what India has achieved so far regarding the control of cybercrime. Toyo (2017), Okeshola & Adeta (2013) and Omodunbi et al. (2016) are also relevant as they provide instances of what happens in selected places in the three major regions of Nigeria. Unlike them, however, the current paper is not restricted to a particular region in Nigeria but focuses only on individual and societal cyber-attacks.

Two of the studies being discussed here concentrate on the professional aspects where the negative impact of cybercrime is felt. These are Aribake (2015) and Ojeka et al. (2017). Aribake (2015) examines the effect of ICT tools in curbing cybercrime in Nigerian commercial banks. According to the study, ICT in banks has both advantages and disadvantages. It enables competition among banks for the optimum delivery of services. However, the major snag is security, in which case, depositors' confidential information is at risk of abuse by criminals. This is a great challenge to Nigerian banks and their customers. Although Nigerian banks use different facilities to protect their businesses from fraudsters, these have very little effect and make online banking difficult and intricate. Hence, economic fraud and internet scams, among others, are manifest. Worse still is the insufficiency of electricity and telecommunication facilities, which consequently limit the improvement of online banking in Nigeria. Nevertheless, there has been a stupendous growth in the use of phones in Nigeria; but this has also facilitated an increase in cybercrime in the country. The study concludes that cybercrime is difficult to combat due to its complex nature and suggests the use of 'a unified and synchronized tactic encouraged by dynamic ICT security system' (p6). The study canvasses the preparation of a cyber-activities guideline to protect bank customers' interests.

In the same vein, Ojeka et al. (2017) examine the nature and dynamics of cybercrime and its contribution to the socio-economic development challenges in Nigeria. Anchored on Risk Theory, the study observes that the Internet revolution and the advent of mobile phone technology in Nigeria have posed unintended challenges to the country. It argues that widespread cybercrime in Nigeria tarnishes the country's image, discourages foreign investment, and reduces people's confidence in digital economy. Hence, it recommends the inclusion of security experts among audit panels, the establishment of laws and capacity building of security experts on contemporary cyber technology. Okeshola & Adeta (2013) also recommend training law enforcement agents while Chawki (2009) suggests strengthening the law against cybercrime and Boniface & Michael (2014) recommends technological innovation to identify internet users.

These studies are also relevant to the current study in that they discuss different forms of cybercrime in Nigeria which the current study is examining from different personal and social perspectives. The focus of this study is on individual and social cyber-attacks.

FOCUS OF THE ARTICLE

Data collection was in two categories. The first category of data was sourced from recalled personal experiences of attempted attacks (through phone calls, text messages and Facebook) on the researcher. The second category of data came from reports by individuals on social media such as WhatsApp, Twitter, Facebook and Nairaland Forums, some online newspapers (*Premium Times*, *National Helm* and *Pulse*) and a blog (www.ladiesgist.com). While Facebook and Twitter are online forums with members from across the globe, the WhatsApp platform and Nairaland Forum are populated principally by Nigerians. Nevertheless, there is a handful of non-Nigerian participants on Nairaland. Stories are taken from the archives of these online sources for discussion and/or exemplification of cases. Data are analysed descriptively.

Fraudulent Phone Calls

Cell phones are very useful in communication. Instead of travelling several kilometres to get or deliver some information, one can easily use the phone to request or pass on information and avoid the stress of travelling or even accidents on the road. However, this facility has been abused by criminals. The first part of it is that a criminal may look for a potential victim's number and call him or her with a hidden/private number. The criminal could then address the receiver usually by their first name or any name that people usually call them. Then, he (in my experience, the callers have always been males) would encourage the receiver to take a guess as to who their caller 'friend' was in Britain, America or such other fanciful places. The naïve receiver may mention a name, and pronto, the con man will latch on to it. He would exchange banter with the receiver briefly before stating 'the business offer' that prompted him to call. It may be a supply of goods to an agency or some kind of contract. If the receiver shows eagerness, the caller will ask him to call him back and hang up. In this process, the would-be victim may be asked to bring some initial deposit to facilitate the order and supply. This researcher has received up to five of such calls at different times. This fraudulent practice attempts to exploit the target's potential greed. If the target is greedy, they would be calculating the gains on the supply instead of the manner the business came about. In so doing, they fall into the trap and get duped.

A participant on Nairaland Forum also narrated his experience of attempted scam through phone about how a fraudster requested to buy property worth 7 million naira from him and the fraudster claimed he was ready to transfer the money to the seller without any prior contact on phone or physically. The second day, the fraudster changed his mind and said he would send the cash by road, but that it would be concealed inside a refrigerator. The day the money was expected, the seller got a call from a 'driver of the vehicle' ostensibly conveying the refrigerator that he had been stopped by the police at a checkpoint, and that the police were demanding N80,000.00 bribe before they would allow the vehicle to pass; otherwise they would open the content since they suspected that it was carrying ammunition for use by the Boko Haram insurgents. The seller who had seen through the deceit told them his phone data was exhausted and requested that he be sent a recharge PIN of N1000.00 to enable him to send the money to the account sent to him. The fraudsters realized that he had blown their cover and hailed him for being intelligent. The fraudsters played on the general belief that the police were corrupt. They expected that by using this trick, the victim would quickly send money to bribe the police, since the mount is far less than the 7 million naira he was supposedly going to earn. It follows that in all financial transactions, people must reason well before taking some decisions in order not to fall into such traps.

Another form of the use of phones is text messages. A message can be sent to a target bordering on certain issues in the society. While the communication networks in Nigeria were offering promotion services to subscribers, the researcher had got text messages from each of his MTN and Glo lines that he had won a million naira in each. He was assigned a serial number and asked to call a particular number to redeem his prize. When he called, the scammer told him that he must first buy a 48,000.00 naira worth of recharge cards and send to the scammer. When queried that it was supposed to be a prize which could have been transferred easily into the winner's account, the fraudster said the money the researcher was being requested to pay was for 'processing'. When told to take the money for processing from the winning, he said the prize would not be released until it was processed. The researcher went to report to his bank the second day and he was told they were fraudsters. If he had been eager to get the prize he neither participated in nor worked for, he would probably have fallen victim. Again, the fraudster is playing on the victim's intelligence, gullibility and, possibly, greed.

Another form of text messaging has to do with Bank Verification Number (BVN). Every account holder in banks in Nigeria is expected to have a BVN. This enables government to monitor cash flow in and out of customers' accounts. However, criminals often used this to collect information from account holders and subsequently steal their money. Fraudsters send text messages to account holders informing them that due to BVN problems, their accounts have been blocked and that the bank customers will not be able to use their Automated Teller Machine (ATM) cards any longer. To solve the problem, such bank customers are advised to call a number supplied in the text message. This is impersonation /identity theft in practice. Fraudsters assume the position of bank staff and request vital information such as Personal Identification Number (PIN) of ATM cards, BVN and other relevant resources that will enable them to get into people's accounts and fleece them of their money. To protect customers, however, banks often advise them not to divulge their secret/relevant information to third parties. In cases where bank customers are in doubt, they are to contact the bank. This kind of text message from fraudsters is playing on the intelligence of the bank customer. An unintelligent or careless customer may lose money through this scam.

Some other text messages can target positions. In a society where one lobbies and sometimes pays to get something, a naïve person would consider himself or herself lucky to have a message sent to him offering them a chance to be minister in a central government. Given the researcher's status as a university lecturer, some crooks sent him text messages that the presidency was considering him for a ministerial appointment. He was asked to send his CV to a mail and call a number. He did not. Sometimes later, he received a call conveying the same message; he rebuked the caller. Again, he got another text message on the same subject much later. The fact is: the researcher believed that if the presidency needed his services, he would get an official letter, not text messages. He probably escaped the hook because he knows the procedures such invitations should take; and especially because he was not eager to jump at offers, regardless of their worth. If he had acceded to their request to submit his CV, the fraudsters would probably have picked some new pieces of information to make money out of him.

Scam E-Mails

Fraudsters also explore the e-mail facility to dupe unsuspecting victims. A colleague travelled to Germany. Criminals hacked into his e-mail account and, posing as the lecturer, used it to send a message to his student in Nigeria that she should send some money into 'his uncle's account' on his behalf. When the student asked her supervisor, he denied ever sending such a message. In this case, the fraudster wanted to exploit the mutual respect that normally obtains between supervisor and student. If the student had not

been bold enough to find out the truth, she would have fallen victim. So, criminals also explore identity theft and our culture of respect to defraud citizens.

Criminals send spam mails to undisclosed recipients claiming that some money had been deducted from their accounts because of certain bank products they had purchased. Here are examples from my yahoo mail box:

1. Dear Customer,
 Thank you for successfully SUBSCRIBING For Diamond Mobile App bull monthly Bulletins.
 We are processing to debit your account with the sum of 20,5000 NGN as our monthly charge for the subscription as per ur terms and conditions.
 If you are not aware of this subscription and Wish to Cancel this, kindly follow our website link below to unsubscribe.
 Note: To unsubscribe, A mobile code will be sent to your registered mobile number to Cancel After Security Validation....
2. Dear Customer,
Your DiamondOnline (MOBILE BANKING) Account will be BLOCKED due to too many Login attempts. Kindly Click Here to RE-VALIDATE to avoid Account Suspension within Hours. A code will be sent to your registered mobile number with us, kindly fill in the code to complete the process.

These messages purport to come from the different banks stated in the mails. The snag is the researcher does not have any account with these banks. It is obviously the work of fraudsters who want to obtain relevant PIN numbers to cash away unsuspecting bank customers' moneys. A closer look at the messages show they have attempted to clone the banks message template. However, the informal language *as per* and cyber language *ur* (ex 1), multi-coloured graphics and the misapplied punctuation (especially on 20,5000) as well as the emphasised threats easily give away the fraud in the mails.

The researcher has also received several e-mails purporting to originate from distant lands such as Burkina Faso. The writer is usually a government official who had stolen some money and wanted 'us' to start a business with it in Nigeria, or a widow who lost her husband in gruesome circumstances but is now looking for a safe haven to invest her inherited money, or an orphan who inherited stupendous money. The writer would claim to trust the recipient such that they could do business together. The first indication that it was fake would be the problem of grammar or mechanics of language generally. The second aspect is the logic behind the set up: why would a total stranger trust completely someone she or he had never seen? These are the major considerations on why the researcher never bothered to pursue any of them. Another variant of this is the mail that requests friendship. The author of the mail, usually with a photograph of a beautiful lady may request friendship from the target victim. Again, this comes across as working on the usual weakness of some men. The researcher is not aware of anyone he knows who fell for this scam. However, the fact that it was rampant at a period suggests that some people did fall for it. Here is an example of such mails directed at people seeking love:

3. We are going to help you find sexy females between the ages of 19 and 25 that want to fuck!
 This is going to sound crazy, but it's the real thing.
4. They are eager to meet new men today. They are sick and tired of dating guys that cannot perform in the bedroom. [Come check their profiles here](#)

The eager juvenile may jump at this offer. If it turns out to be true, another juvenile is corrupted. A click on the link leads to pictures of stark-naked females. The questions on the page enquire whether one is up to 18, whether one is ready to abide by the condition that the women did not want any relationship, whether one agrees to use condom and whether one would not reveal the identities of familiar faces among the ladies. One has to click YES or NO on each question as a form of answer. However, whichever one clicks, one is still allowed to continue browsing! This means that the questions are just cosmetic; they serve to deceive new entrants into the world of prostitution or pornography.

Sometimes, the intent is not to immediately get money, but to get access to crucial information. Fraudsters may send mails to individuals that their mail accounts (such as yahoo) had to be closed down due to a request they had made. The account holder would then be advised to click a link to stop it if they did not want it closed. It would be emphasised that the account holder would lose all the contents of the mail box. Experience has shown that all the threats in this kind of mail never came to pass. No one deletes the account; one only falls into a trap if one proceeds to click on the link.

A scam mail can also be in form of a blackmail. The author may accuse the owner of the account of visiting some adult sites, quoting IP address of the target dupe's browser. The author may request that a specified amount of money be paid into his or her bank account, otherwise, pictures from such places visited by the addressee would be packaged and sent to all contacts in the person's mailing list. The idea is to blackmail that person into paying the criminal. The fact is that only the guilty may feel jittery; the innocent will not. The writer is playing on the possibility that the addressee will fall into the category of people that visit adult sites. Such people who may not want other people to know about their dirty secrets may quickly pay. However, they always forget, or do not know, that blackmailers never desist.

Cyber-Attack Through Leaked Video Messages/Pictures

There are several cases of leaked video messages and photographs. These are in different categories. The first category is that of husbands who caught their wives cheating. Video recordings of such cheating men and women are made and posted on the Internet. In another case, some secretly recorded videos of important personalities/celebrities and their partners are often released to the public to embarrass the target victims for whatever reason known to the poster. It may be for purposes of blackmail or a revenge if the victim is considered too powerful for the person that posted the video.

Sometimes, technicians who repair laptops, tablets and phones have also allegedly released nude pictures of their clients to the public through the Internet. They often claimed they stumbled on the pictures in the gadgets, but they have not confessed that they were blackmailing the owners of the videos. A university professor was once caught in the web¹. A female student of his got hold of his phone and asked him to send her huge sums of money. When the professor refused, his nude photographs were displayed on the Internet. The student's claim was that he had been sexually harassing her while she was taking his courses. The university administration set up a panel to look into the matter, but the complainant did not show up to defend her claim!² Some disgruntled boyfriends also released nude photographs of their former girlfriends to the public via the internet. Usually, this happens when the girlfriend dumps the boyfriend. These are acts of human rights abuse by individuals.

Nevertheless, some people deliberately post raunchy photographs of themselves on the web to attract people to their profiles. The females are usually nude or half nude, showing the curves of their body in the pictures. Some claimed to be looking for sex partners while others were just 'expressing themselves'. Some of the photos were taken in nudity by couples who had just made love; some by teenagers in undergarments. The problem with this is that it encourages immorality among children and adolescents

who may stumble on such posts, thus debasing our cultural values. Although the intent is different, it is mild pornography which may fascinate children and encourage them to practise same. It has a corrupting influence on children, encouraging moral depravity.

Cyber-Attack Through WhatsApp Messages

WhatsApp is a social media platform where participants exchange ideas. Many messages are posted and re-posted to friends or forwarded to other group platforms such that by the time a message gets to one, its source may not be traceable. Criminals have keyed into this area too by posting fake vacancies on the WhatsApp forum to attract job-seekers to their den. The following is a warning against such vacancies.

5. BEWARE! DON'T ATTEND ANY INTERVIEWS AT THIS ADDRESS.

Olabisi Close, MENDE, Maryland (Lagos Resident only) hr
080-7464-5567
Please beware of this Address
They are Kidnappers and ritualists...
Kindly spread it. We never know who we might save. Sent as received.

This text rests on the shared knowledge among Nigerians about the existence of ritualists. Ritualists in Nigeria are dangerous people to whom kidnappers sell kidnap victims. Ritualists are said to use human beings or human parts for rituals or charms. So, people visit ritualists to make money rituals or charms that will enable them to win elections into their desired public offices, make them extremely rich or get something extraordinary. Given the text above, readers, especially job-seekers, are warned not to visit a particular address in Lagos to avoid falling victim of ritual killing. Perhaps, this is a rider to the account of a woman who went for an interview in a secluded place. She escaped through a tip-off from a member of her church who happened to be a gateman in the house. The issue here is that fraudsters exploit all situations, including joblessness to make money at all costs. They remain faceless and difficult to apprehend because of the anonymity provided by the internet.

Sometimes, some seemingly innocuous messages on WhatsApp turn out to be links to gambling websites. For instance, the following messages were posted on WhatsApp, but the links lead to gambling sites:

6. OMG! Have you seen this? xxxv.xxuxi.com³
7. See this now xxx.xxvxa.com

The messages look harmless and seem to lead to a great opportunity that someone may want to see. However, they actually lead to gambling websites. This is a means of luring unsuspecting youths into gambling.

On Nairaland, there are regular invitations to members to meet 'sugar daddies' or 'sugar mummies'⁴ with promises of money. Interested persons' phone numbers are normally requested. Since it is now widespread, it is no longer strange to have requests for sugar mummies on Nairaland. However, it is believed that such sugar daddies and mummies use charms to 'steal the destined fortunes' of people who make love to them or that they make love to.

Cyber-Attack Through Facebook

Facebook is a bigger forum than the WhatsApp. The first observation of fraudsters' antics is that they would send a friend's request. A careful user of Facebook would look at the profile of the would-be friend. For normal person's Facebook account, the profile will be populated with different stories or activities. For fraudsters, they have very scanty information on their profile pages. In some cases, faces of white people are used as display pictures. One thing is certain here: the photos were stolen from some online web pages and reused. This is identity theft. In addition, they try to legitimise their identity by seeking friendship with normal innocent people. Once that is achieved, they start their nefarious activities. One way is to try and seduce the target.

A poster on the Nairaland received such an invitation and accepted the friend request of a supposedly white lady, who claimed to be chatting from London. In the course of their conversation, she requested webcam chat, but the poster said his laptop had problems with video call. She requested his phone number and home address, and he supplied them. The lady then told him that she had sent him a package containing a laptop through a company called RM Logistics Courier Service. She claimed to have paid for the export tax and transport, but that the company policy denied her payment for the clearing, and that the receiver was to pay for that. In lieu of that, she claimed to have hidden £400 inside the keyboard of the laptop. She advised the recipient to clear it since the company does home delivery. She sent a picture of a beautiful golden Apple laptop. Thereafter, she wrote that she placed an iPhone inside for him as a surprise. She advised him to expect the company's call on Thursday.

For a poor, unemployed or greedy person, this may be seen as a gift from a benevolent person. However, a reasoning fellow would wonder what benefit the white lady would derive by giving out such gifts to a total stranger. The second issue is that she claimed to have hidden 400 pounds in the laptop. Apart from its illegality, when the money is converted to the local currency, it amounts to about ₦185,000.00, an amount sufficient to buy another laptop in Nigeria! This is an appeal to the greed of the recipient. A greedy person may not think of clearing alone, he might think of the huge sum and what he could do with it after clearing the laptop. Finally, perhaps as an afterthought, she claims to have included an iPhone, a very expensive phone, as a surprise. Since she has already said so, is it still a surprise? The real intention is to appeal to the target's greed and brainwash him to desire the package very much. And the company whose name is fake cannot be located. If there is need to invite the police or go to court, there is no name or address attached to the company.

The poster narrated this experience on the Nairaland Forum for advice because he suspected it was a scam⁵. Members confirmed his fears. They said it is a regular means of scamming people. One member said her friend lost ₦40,000 in a similar scam. The recipient will be milked of any amount of money criminals can get from him and he will not get any parcel eventually. One person also noted that the white lady's use of English did not look like that of someone in London; it was a Nigerian variety of English.

Another poster brought a related matter to the Nairaland forum⁶ he was duped to the tune of ₦12,000 by a Facebook friend who promised to get him a job. He was asked to pay some money in advance. Still on Nairaland, scammers dupe people of their money through games. A dupe got a fake game he played in gambling and lost despite all assurances. When the dupe complained, he was promptly removed from the WhatsApp group chat⁷. In a related development, a man who paid to buy data online was also duped. He transferred the requested amount into the scammer's account but the scammer did not send the data paid for⁸.

Facebooks accounts are also hacked such that hackers assume ownership of the account. Such fraudsters send messages to contacts on the account claiming to be at one meeting or being stranded at a place where they cannot get recharge cards to buy. Such contacts are then requested to send recharge card numbers online for the fraudster to change to liquid cash thereafter. Some gullible people fall for this scam; some do not, requesting that the Facebook friend (assumed by the fraudster) send his or her phone number and that they would credit it directly or send the recharge card PIN into it. Some people also impersonate other people for nefarious activities. A man allegedly opened a social media account in Godson's name to defraud his unsuspecting fans. He lifted Godson's videos and photographs and used them to convince his targets and then proceeded to ask for their nude photographs⁹. This is a case of identity theft.

The Facebook is also used to lure people into places where they are violated or used for rituals. Many accounts exist where a male will request friendship from a female online. After she accepts, they will keep chatting and, in the process, arrange for a date. When the target shows up, they are usually molested by many males or decapitated for sale to ritualists. Gory tales of these appear on Facebook and in newspapers. Some that escaped such attacks exposed the modes of operation of such criminals. There was the case of a university student who became friends with a man she met on Instagram.¹⁰ When they met in a hotel, she was drugged and abused. The man took photographs of her state of nudity and recorded the sex sessions on video. These later became tools for blackmail. This is abuse. However, the man was later arrested by the police.

It is also becoming widespread that lovers will meet and have intimacy, but the male partner will record the acts and later use it for blackmail. Two ladies were drugged and violated when they visited a man one of them had met via Facebook. The man and his friend who was with him when the girls visited made a video of their love sessions and posted it on the WhatsApp and it later got posted on a porn site¹¹. In another case¹², a lady got very emotional with a man she had met only on Facebook. She sent different nude photos to him. The man turned around to request a video call with her posing nude, and threatened to post her nude pictures which he had on the Internet if she did not oblige him¹³. The only saving grace is that the police are catching up with the criminals, provided the victim is bold enough to report the case. Nevertheless, the acts constitute an abuse of the internet, a cybercrime.

A subtle part of it is that young females, usually claiming to be undergraduates, often request friendship from random males on Facebook. They easily agree to advances from the males. In the process, they request transport fare, purportedly to take them to the man's house for a date. Since the initial request is often little, say, as low as N3,000 for a long-distance trip, an unsuspecting man may pay the money into the bank account provided by the female. After payment, she may make further requests until the male gets frustrated and wakes up to the reality that he has been duped. Another aspect of it is that some female university undergraduates use this medium and method to engage in subtle prostitution, called 'runs'. Having made contacts on Facebook, they offer sex for money to random males, charging according to the ability of the client.

Online materials abuse is also capable of dehumanising the youth. A 27-year old Microbiology graduate and Nairaland user recounted how she accepted a friend request of an Indian man, exchanged nude pictures with him and also engaged in video chat with him.¹⁴ Now, she is addicted to it and masturbates any time she is alone, even when in church. She feels guilty, and cries out for help. This person used the cover of anonymity provided by the Nairaland forum to shout out. We may not know now how many other victims of this kind of abuse are suffering in silence.

Fraudsters can also play on the intelligence of humanitarian people. A scammer posted a photo of a very sick child, claiming it had congenital heart disease, and asking for ₦12.000 to balance the money he already had¹⁵. Beside the child's picture, the scammer posted what looked like a medical report on the child. Medical doctors on the site enlightened online readers that the medical report was fake; in fact, it was gibberish! The scammer had tried to hoodwink people with the squiggles on the paper since doctor's handwritten reports are usually illegible to lay people.

Finally, there is also the aspect of cyber bullying on Facebook. A private school owner had sought advice regarding how to solve a particular problem in the school she managed from members of her group on Facebook. Rather than give the advice she requested, commentators took her up on her incompetence in the use of the English language. She was thoroughly humiliated. Eventually, she wrote, bemoaning her fate and announcing her withdrawal from the group. That was the result of cyberbullying.

Advertising

For the purposes of celebrating birthdays, some may upload their nude or half nude pictures on the social media. They are quite oblivious of the harm they are causing the society, especially the youths. An example is the story of a girl dressed in bikini whose pictures appear in *National Helm*, an online newspaper¹⁶. Any youth that comes across the photo may want to emulate her. However, this is cultural degradation. Traditionally, the underwear is supposed to be worn underneath the clothes. Now, this culture has been debased to the extent that its abuse is now displayed on the social media. The question is: what do ladies gain through this act? It is simply to let the pictures go viral, such that many social media commentators will *like* it. The more *likes* it attracts, the more satisfied, fulfilled or highly rated the profile owner is assumed to be.

According to a Nairaland thread¹⁷, a lady may start posting on her profile page with decent pictures and stories, and get, say 3 *likes* and 0 comments. Dissatisfied and frustrated, she may post a sexy picture (possibly wearing a skimpy dress in the picture) and get 50 likes and 20 comments. Encouraged by the results, she may take a picture at the pool where she's dressed in only bikini, and the result may go up to 450 *likes* and 100 comments. This encourages her to post more revealing photos and write more morally depraving stories on her page. She becomes insatiable and continues to post more revealing pictures of herself just to get the attention she desperately desires. The cybercrime world has thus successfully won another convert!

Perhaps, the most brazen acts came from a woman who posted a video of herself engaged in acts of lesbianism; and a student who uploaded her nude pictures and masturbation video.¹⁸ Another lady has also put her nude and erotic pictures for sale at ₦8,000/\$25 each and masturbation videos for \$40 each¹⁹. This confirms the claim that sex sells, but at whose expense?

Perhaps, more worrisome is the fact that some people traffic in women using the social media as advert platform²⁰. Beautiful ladies in different stages of nudity (from partial to total) are displayed on the internet for interested men. The men get across to the organisers and make their choices. The ladies travel to any place their 'services' are required at a fee. Although it is based in South Africa, it targets Nigerian clients. According to the www.ladiesgist.com blog, the organisation used the name Feline Management and Innovative Models as a smokescreen to shroud its activities. Curiously, some of the girls may not know they are being pimped; they get to know when they experience carnal abuse by clients. At the extreme, they may disappear without any trace or be found dead. A commentator to the blog said she was molested continuously by 6 men and given R20,000, and the organisers paid her 'to keep quiet'. She took the money and said nothing because she was too ashamed. Just like Feline Management and

Innovative Models, Social Exchange Market is alleged to be pretending to be a charity organisation.²¹ The organisation is said to be scam like the defunct Mavrodi's Ponzi scheme where members were encouraged to pay in some money to receive multiples of their investment in a short time.

Another incident was a job scam²². The victim applied for a job advert placed on Nairaland and was interviewed on phone. He was asked to do a medical test of fitness and given an account to pay the test fees into. Once he paid the amount, he realized he had been duped: there were no tests and no job!

Cloning of Financial Instruments

Many atrocities are carried out at different ATM spots. One of them is cloning. Users of the machine may just insert their cards into it to withdraw money oblivious of the fact that some fraudsters had programmed the machine to store their card's PIN numbers. After the users leave, the fraudsters will come back to retrieve the number, make a duplicate copy of the cards and use them to withdraw all the money in the accounts. Hence, users are advised to cancel previous transactions before inserting their cards. Cancelling previous transactions is expected to wipe off any pre-programmed cloning device that could have been installed on the ATM.

Cloning is not limited to ATMs. Some people had bought things and paid by using their ATMs on POS presented to them at shops and supermarkets. Some of such cards had also been cloned and the victim's money stolen. A vigilant vehicle owner prevented this from happening to him when he caught petrol station attendants trying to duplicate his card number. The need for vigilance in this kind of transaction cannot be overemphasised.

SOLUTIONS AND RECOMMENDATION

The first piece of advice is that one should not disclose any personal information or send one's photos to strangers online as they may be misused. Jack et al. (2016: 46) observe that victims "are usually the gullible, greedy and inexperienced and those desperate for quick money or love and relationships". They advise that individuals should observe safety rules by not revealing personal information and banking details to strangers.

One should also watch whatever one's children are doing on the Internet and use content filtering software on their computers (Jack et al. 2016). This will enable parental guidance and advice. Kamini also advised that people install latest antivirus and update them regularly to guard against attacks; and back up data in order to avoid loss in case of virus contamination. Web site owners are advised to install a security programme that gives control over cookies and sends information back to the site; and put host-based intrusion detection devices on servers.

In addition, the public needs to be educated on the existence and negative effects of cybercrime. Hence, jingles should be aired on radio and television to educate the public on how to identify cybercrimes and subsequently avoid being duped. This will not only protect the innocent people, it will also discourage fraudsters engaged in the crime. They should also be taught on how to avoid playing into the hands of fraudsters. Such acts include protecting their systems from cyber attacks, avoiding suspicious offers and protecting their financial and other relevant information from the public glare.

Individuals should also control their greed as well as love for money and the opposite sex. They should also not jump at seemingly good offers, especially from total strangers. More importantly, they should study online documents carefully for grammatical correctness and reasonable propositions, as these may give clues to identifying fake proposals.

It has also been suggested that every Nigerian should report cybercriminals regardless of their social affinity. Corporate bodies are advised to pool resources together to fight cybercrime, a common enemy, and protect their Internet resources and safeguard their operations through appropriate mechanism. They should sponsor bills against cybercrimes to enhance their business. The government is also advised to make more stringent laws and prescribe punishments to offenders (Idoko & Ugwuanyi, 2015). One of these is forfeiture of the proceeds of the crime to the government.

Government should further strengthen the Cybercrime Act of 2015 to ban wanton display of raunchy materials capable of destroying the youths of the nation. Although there is a section on ban of child pornography, a clever lawyer may claim that photographs in bikini do not constitute child pornography. Hence, the law needs to be strengthened as new cases of cybercrime or abuse come to the fore. Government should also provide adequate training to law enforcement, intelligence and security agencies on how to track down offenders (Okeshola & Adeta, 2013)

Finally, Boniface & Michael (2014) propose a design to monitor internet users' activities in order to curb cybercrime. This involves redefining the operations of Internet Service Providers (ISPs) which requires authentication of users before they access the Internet. This is expected to ease monitoring and apprehension of Internet offenders.

FUTURE RESEARCH DIRECTIONS

This study has discussed some aspects of cybercrime perpetrated on some social media platforms largely as reported on Nairaland. It would be necessary to conduct research on individual members of the platforms to provide first-hand experiences of cybercrimes they have had. Perhaps, we will get to know the ramifications of the problem and the government will be better advised on how to stem the tide. It may also be necessary to study other online platforms such as Eskimi, 2go, Twitter and Instagram in detail. A proper scrutiny of participants may yield great revelations about cybercrime in these places.

CONCLUSION

From the foregoing, we can make some inferences. The first thing is that cybercriminals assume a particular identity plausible enough to the target victim. Fraudsters get close to the target victims, sometimes use terms of endearment and generally make themselves acceptable to the would-be victims before they start the process of attacking them. They may exploit different situations such as unemployment, greed, stupidity, poverty or promiscuity to get close to the target. Once they get the target's weak point, they latch on to it and execute their plans.

Again, some targets become pawns in the hands of fraudsters because they are also dishonest, gullible, impatient, careless or carefree. Some people like the allure of the world, while some want to show their elevated status by assuming absolute knowledge of goings-on on the internet. In so doing, they hide information from friends and colleagues who could advise them. Yet, some are also selfish as well as greedy, such that they fall easy prey to the whims of the cybercriminal.

Some internet users are not computer savvy, but to acquire their practical computer knowledge, they go online and fall into traps. Some did not want to watch pornography, but they stumbled on it and got hooked; some wanted to show off their beauty, they ended up overdoing it and getting into wrong hands. Yet, some want to become a celebrity overnight; they attract dangerous elements to themselves by what they post. More worrisome is that many youths have sophisticated phones and because they are free from the public glare and from parental and other controls, they launch themselves into the Internet, unaware of the many cybercriminals prowling the web space. They all make themselves easy target for criminals.

Finally, many parents have relaxed their vigilance on their children or wards. They are negligent in their parental duty and their children, in the name of civilization, do anything they desire. It seems that a level of observation of the traditional/cultural norms which preach decency and modesty in what one does could save some children if they adhere to the culture.

These are weaknesses that the cyber-criminal exploits to attack individuals and the society. Each Nigerian ICT user should be careful and use the internet intelligently. Users need to guide against such attitudes to be free from cyber-attacks.

KEY TERMS AND DEFINITIONS

Cashless Policy: A policy that discourages the use of huge raw cash for transactions but encourages the use of bank transfer, ATM card, POS, and other financial instruments for transferring cash in transactions.

Cloning: Creating a replica of websites or cards with intent to defraud.

Cyberattack: Any form of injury done to a network or individual through the internet (e.g., cyber stalking, cyber bullying, and malware).

Cybercrime: Any crime committed using the ICT platform. These may be child pornography, phishing, cyber terrorism, etc.

ICT: Information communication technology; involving the use of computer, phones, and the internet in managing information.

Identity Theft: Assuming the identity of another individual by using their photographs, profiles, or e-mail accounts to act in their capacity for nefarious activities.

Netrespass: Infiltrating another internet user's space and carrying out unauthorised activities (e.g., trespass).

Victim: The individual or entity that suffers the effect of cyberattacks.

INTRODUCTION

Cyber security has become an important subject of national, international, economic, and social importance that affects multiple nations (Walker, 2012). Many countries have come to understanding that this is an issue and has developed policies to handle this in an effort to mitigate the threats (Dawson, Omar, & Abramson, 2015). To address the issue of cyber security, various frameworks and models have been developed. Traditional approaches to managing security breaches is proving to be less effective as the growth of security breaches are growing in volume, variation and velocity (Bhatti & Sami, 2015). The purpose of this article is to show what future cyber security as engineering science and technology expects. In addition, the authors propose future solutions for the use of computer with a Sleptsov Net-processor when it will be actually created and practically implemented. The authors of the article did not consider the credibility issues of Sleptsov network computing but completely trusted the creator of Sleptsov net as a processor, based on open sources, in particular on publications and webinars of IGI Global (Zaitsev, 2016; Zaitsev, et al., 2016; Zaitsev, 2018). Based solely on these publications the authors research the emerging trends and perspectives of digital transformation of the economy using machine learning with avatar-based management at the platform of Sleptsov Net-processor and propose further prospects for development of hyper-computation (Mkrttchian, et al., 2019).

BACKGROUND

Many researchers compare machine learning solutions for cyber security by considering one specific application (e.g., Buczak and Guven, 2016; Blanzieri and Bryl, 2008; Gardiner and Nagaraja, 2016) and are typically oriented to Artificial Intelligence experts.

DOI: 10.4018/978-1-5225-9715-5.ch070

The term “cyber security” refers to three things:

1. A set of activities and other measures, technical and non-technical, intended to protect computers, computer networks, related hardware devices and software, and the information they contain and communicate, including software and data, as well as other elements of cyberspace, from all threats, including threats to national security;
2. The degree of protection resulting from the application of these activities and measures;
3. The associated field of professional endeavor, including research and analysis, aimed at implementing those activities and improving their quality (Jenab, et al., 2018).

At the same time, our previous research of the problem of cyber security showed that cyber security is a section of information security, within the framework of which the processes of formation, functioning and evolution of cyber objects are studied. It is necessary to identify sources of cyber-danger formed while determining their characteristics, as well as their classification and formation of regulatory documents, implementation of security systems in future. However, working on the application of the machine learning for Cyber Security applications with the use of developed by the authors Avatars-Based Management techniques, we came to the conclusion that this is not so, and the built-in cyber security systems can be destroyed by the same artificial intelligence.

The search for a solution to this discrepancy leads to a thought about advantages of natural intelligence displayed by humans where everything is interconnected, logical and protected (Mkrttchian, et al., 2015).

This paper is specifically aims to research the emerging trends and perspectives of cyber security development in the conditions of digital economic transformation using machine learning with avatar-based management at the platform of Sleptsov Net-processor, and to identify their main limitations.

Sleptsov net concept mends the flaw of Petri nets, consisting in incremental character of computations, which makes Sleptsov net computing a prospective approach for ultra-performance concurrent computing (Zaitsev, 2018).

A Sleptsov net (SN) is a bipartite directed multi-graph supplied with a dynamic process (Zaitsev, 2016). An SN is denoted as $N=(P,T,W,\mu_0)$, where P and T are disjoint sets of vertices called places and transitions respectively, the mapping F specifies arcs between vertices, and μ_0 represents the initial state (marking). The mapping $W: (P \times T) \rightarrow N \cup \{-1\}$, $(T \times P) \rightarrow N$ defines arcs, their types and multiplicities, where a zero value corresponds to the arc absence, a positive value – to the regular arc with indicated multiplicity, and a minus unit – to the inhibitor arc which checks a place on zero marking. N denotes the set of natural numbers. To avoid nested indices we denote $w_{ij} = w(p, t)$ and $+ =$. The mapping $\mu: P \rightarrow N$ specifies the place marking (Zaitsev, 2018).

Based on the previous research, performed by D. Zaitsev (2018; 2019), the main conclusion was drawn that Sleptsov networks are executed exponentially faster than Petri nets that makes it possible to recommend them as a parallel computing model for subsequent practical implementation.

Calculations on the networks of Sleptsov acquire all new applications presented in the works. First of all, computations on Sleptsov networks may be used for those applications in which parallel programming style can bring significant acceleration of computations.

Effective practical implementation of computations on Sleptsov networks requires the development of appropriate specialized automation systems for programming and hardware implementation of processors of Sleptsov networks. In addition, further development of theoretical methods of proving the correctness of programs in the language of Sleptsov networks and the development of universal networks that use mass parallelism are needed.

The advantages of computing on the Sleptsov networks are visual graphic language, the preservation of the natural domain parallelism, fine granulation of parallel computing, formal verification methods for parallel programs, fast mass-parallel architectures that implement the computation model (Zaitsev, 2018).

FOCUS OF THE ARTICLE

Machine learning (ML) was introduced in the late 1950's as a technique for artificial intelligence (AI) (Ambika, 2018). Over time, its focus evolved and shifted more to algorithms that are computationally viable and robust. One of the classical definitions of Machine Learning is the development of computer models for learning processes that provide solutions to the problem of knowledge acquisition and enhance the performance of developed systems (Duffy, 1995).

Machine learning is the use of artificial intelligence (AI) that provides systems with the capability to learn and automatically improve from experience (data) without being explicitly programmed. Machine learning focuses on developing computer programs that can access data and use them to learn by themselves.

Ideology of Machine Learning based on the principles of multiple use (reusability) and free distribution (share ability) copyright courses. Therefore, developers of training courses must adhere to generally accepted standards. To date, the most widely used models of the following courses:

1. Model IEEE LOM (Learning Object Model), developed by the LTSC (Learning Technology Standard Committee) in 2002. The entire set of learning objects is divided into 9 composite hierarchies (categories): General (General), life cycle (Life Cycle), metadata (Metadata), technical (Technical), education (Education), legal (Rights), communication (Relation), annotation and classification (Annotation and Classification).
2. System specifications consortium IMS (such as egg Content Packaging Specification, Metadata Specification, Digital Repositories Interoperability, Digital Repositories).
3. Specifications Committee AICC (Aviation Industry Computer-Based Training Committee) originally intended for the development of computer-based training systems and technologies in the aviation industry.
4. Specification SCORM (Shareable Course Object Reference Model), developed in the framework of the ADL (Advanced Distributed Learning), carried out by the Ministry of Defense. This is the industry standard for exchange of training materials based on tailored specifications ADL, IEEE, IMS. AICC. SCORM is the basis of the model modular design of educational material by separating the individual autonomous educational units (SCO - Shareable Content Objects) and their representation in the Web- specific repositories. SCO modules can be assembled together in various combinations and compiled into electronic textbooks using LMS- system. Thus, if in the first E-Learning systems, a teacher was expected to collect their own training courses to keep in his personal computer, and then manually organize a nationwide educational content, with the advent of such specifications as SCORM, this work is automated with the possibility of using Web 2.0 technologies and service-oriented approach (Mkrttchian, et al., 2019).

Another pressing problem of modern machine learning systems is the problem of creating a student model based on the tracking of personal information related to learning trajectories passing on various training modules or web-services, the courses tendered tests. For these purposes, there is also a range of specifications, the most famous of which are:

- IEEE PAPI (Personal and Private Information);
- IMS LIP (Learner Information Package).

It uses the language XML (eXtension Markup Language) to write to the user's profile his curriculum vitae, teaching history, language skills, preferences to use computer platforms, passwords, access to training, etc. These data are then used to account for the individual characteristics of the student in determining the best means and methods of teaching.

Competency assessments for learning are also used standardized specifications, which were developed and presented in the recent authors' work (Mkrtychian, et al., 2019). In this work, the authors consider different issues related to the modeling supercomputer with Sleptsov Net-processor to visualize of a report on the work of Cyber Security system.

Having considerable experience in Intellectual Control and Communication, Avatar-Based Learning, Teaching and Training, and Avatar-Based Management, there is a need in modelling a joint system of Machine Learning with Avatar-Based Management with the use of Sleptsov Net-processor.

We define as an Avatar-Based Management (A-BM) model variability hypergraph VMG, consisting of two sets and predicate:

$$VMG = (V, U, P), \quad (1)$$

Set V describes the structure of a hypergraph on the vertex level:

$$V = \{v_{i,(weight)}\}, i = 1, 2, \dots, N, \quad (2)$$

where N – is the total number of peaks is corresponding to the total number of characteristics of the A-BM model variability; weight - vertex weight in form n.1.1.1 corresponding to the index of the corresponding characteristics in the hierarchical structure of the A-BM model variability.

Set U has a capacity corresponding to the number of possible configurations of the A-BM:

$$U = \{u_j\} ; j = 1, 2, \dots, K, \quad (3)$$

where K - the numbers of hyperedges.

Obviously, depending on the size and structure of each elements of Block diagram the Model of Platform of the supercomputer with Sleptsov Net-processor in the Support Cyber Security Applications (fig.2), from the technical and communications capabilities available to the user at some point and some other features of the cardinality of the set U can vary significantly.

Predicates P - determines incidence of vertices and hyperedges of each layer. P is defined on the set of all pairs $(v \in V, u \in U)$. Truth domain predicate P is the set R of variable cardinality $Bt \neq \text{const}$:

$$F(P) = \{(v, u) \mid P(v, u)_r\}, \quad (4)$$

Where $v \in V, u \in U, r \in R = \{1, 2 \dots B_r\}$

Variability of the cardinality of R is due to the same causes as the variability of U in Equation 3.

Considered a set-theoretic representation of the A-BM model to determine the variability of the matrix representation of this A-BM model is useful for creating software for Machine learning application with Avatar-Based Management technique use. Matrix representation (incidence matrix size $N \times K$) hypergraph will have the form (Mkrttchian, et al., 2014) (5):

$$M_f = || m_{ij} ||_{N \times K}, \quad (5)$$

Where:

$$1, \text{ if } (v_i, u_j) \in F(P), v \in V, u \in U$$

$$m_{ij} = 0, \text{ if } (v_i, u_j) \notin F(P), v \in V, u \in U$$

In some cases it is more convenient to use the matrix of connected vertices of the hypergraph (Equation 6), which has a size $N \times N$ and reflects pairwise connectivity relations through vertices incident hyperedges).

$$M_c = || m_{ij} ||_{N \times N}, \quad (6)$$

where:

$$1, \text{ if } (v_i, v_j) \exists u_k, (v_i, u_k) \in F(P), (v_j, u_k) \in F(P), v \in V, u \in U$$

$$m_{ij} = 0, \text{ if } (v_i, v_j) \neg (\exists u_k), (v_i, u_k) \in F(P), (v_j, u_k) \in F(P), v \in V, u \in U$$

The authors developed a Block diagram of the model of platform for supercomputer with Sleptsov Net-processor in support cyber security applications (Mkrttchian, et al., 2019), which allows to implement the hypergraph, in which weights of vertices correspond to indices characteristics in the A-BM model supercomputer with Sleptsov Net-processor model and the hyper-cores correspond possible A-BM model configurations.

CONCLUSION

In this article, the authors studied machine-learning application with the use of Avatar-Based Management technique for cyber security issues. Our previous research devoted to the cyber security problem showed that cyber security is a section of information security, within the framework of which the processes of formation, functioning and evolution of cyber objects are studied. It is necessary to identify sources of cyber-danger formed while determining their characteristics, as well as their classification and formation of regulatory documents, implementation of security systems in future. However, working on the application of the machine learning for Cyber Security applications with the use of developed by the authors Avatars-Based Management techniques, we came to the conclusion that this is not so, and the built-in cyber security systems can be destroyed by the same artificial intelligence (Mkrttchian, et al., 2019).

The author concluded that machine learning with Avatar-Based Management at the platform of the Sleptsov Net-processor is the future solutions to hyper-computations in the support cyber security applications.

KEY TERMS AND DEFINITIONS

Hypercomputation or Super-Turing Computation: Is a multi-disciplinary research area with relevance across a wide variety of fields, including computer science, philosophy, physics, electronics, biology, and artificial intelligence; models of computation that can provide outputs that are not Turing computable.

Machine Learning: Is the use of artificial intelligence (AI) that provides systems with the capability to learn and automatically improve from experience (data) without being explicitly programmed.

Machine Learning Application With Avatar-Based Management Technique Use: Is a class of methods of natural intelligence, the characteristic feature of which is not a direct solution of the problem but training in the process of applying solutions to a set of similar problems.

Shareable Content Object Reference Model (SCORM): Is a collection of standards and specifications for web-based electronic educational technology (also called e-learning).

Sleptsov Net (SN): Is a bipartite directed multi-graph supplied with a dynamic process.

Perspective Tools to Improve Machine Learning Applications for Cyber Security

INTRODUCTION

Today security systems suffer from low detection rates and high false alarm rates. In order to overcome such challenging problems, there has been a great number of research conducted to apply Machine Learning (ML) algorithms (Tran, et al., 2012).

Machine learning techniques have been successfully applied to several real world problems in areas as diverse as image analysis, Semantic Web, bioinformatics, text processing, natural language processing, telecommunications, finance, medical diagnosis, and so forth (Gama, and Carvalho, 2012). Recent definition of machine learning is developed by I. Cadez, P. Smyth, H. Mannila, A. Salah, E. Alpaydin (Cadez, et al., 2001; Salah and Alpaydin, 2004).

The issues of the use of machine learning in cyber security are disclosed in many works (Anagnostopoulos, 2018; Edgar and Manz, 2017; Yavanoglu and Aydos, 2017; Khan, et al., 2014; Khan, 2019; Dinur, 2018). Using data mining and machine learning methods for cyber security intrusion detection is proposed by the authors (Kumar, et al., 2017). Object classification literature shows that computer software and hardware algorithms are increasingly showing signs of cognition and are necessarily evolving towards cognitive computing machines to meet the challenges of engineering problems (Khan, et al, 2014). For instance, in response to the continual mutating nature of cyber security threats, basic algorithms for intrusion detection are being forced to evolve and develop into autonomous and adaptive agents, in a manner that is emulative of human information processing mechanisms and processes (Khan, et al., 2014; Khan, 2019).

The maintenance of cyber security can significantly differ depending on the requirements for the control system, its purpose, the specificity of the managed object, the environmental conditions, the composition and state of the forces and controls, and the management order. Why do we need to distinguish between information and cyber security? What tasks can be achieved with this distinction?

This need is conditioned by the transition to a new socio-economic formation, called the information society. If earlier the problems of ensuring cyber security were relevant mainly for the military organization, in connection with the existence and development of the forces and means of information confrontation and electronic warfare, now such problems exist for the state as a whole.

Thus, the tasks of ensuring cyber security for today exist, both for the state as a whole, and for certain critical structures, systems and objects (Mkrttchian, et. al, 2019).

DOI: 10.4018/978-1-5225-9715-5.ch071

BACKGROUND

Modern economy networking now has become one of the most popular communication tools to have evolved over the past decade, making it a powerful new information sharing resource in world society. It is known, social-economy networking is the creation and maintenance of personal and business relationships especially through online social networking service that focuses on facilitating the building of social networks or social relations among people.

By embracing social networking tools and creating standards, policies, procedures, and security measures, educational organizations can ensure that these tools are beneficial.

The authors in this article show the essence, dignity, current state and development prospects of avatar-based management using blockchain technology for creation of new tools for machine learning applications (Mkrttchian, et al, 2016). The purpose of this article is not to review the existing published work on avatar-based models for policy advice, but to try an assessment of the merits and problems of avatar-based models as a solid basis for cyber security policy advice that is mainly based on the work and experience within the recently finished projects Triple H Avatar an Avatar-based Software Platform for HHH University, Sydney, Australia which was carried out 2008-2018 (Mkrttchian, et al., 2011,2012,2013,2014, 2015, 2016, 2017, 2018). The agenda of this project was to develop an avatar-based closed model with strong empirical grounding and micro-foundations that provides a uniform platform to address issues in different areas of digital economy. Particular emphasis was put on the possibility to generate an implementation of the model that allows for scaling of simulation runs to large numbers of avatars tools and to provide graphical user interfaces that allow researchers not familiar with the technical details of the implementation to design (parts of) the model as well as engineering and economy experiments and to analyze simulation output (Mkrttchian, 2015).

FOCUS OF THE ARTICLE

In this section, we discuss blockchain in relation to the visualization lifecycle including the following phases: identification, discovery, analysis, redesign, implementation, execution, monitoring, and adaptation. Using this lifecycle as a framework of reference allows us to discuss many incremental changes that blockchains might provide.

Process identification is concerned with the high-level description and evaluation of a company from a process-oriented perspective, thus connecting strategic alignment with process improvement. Currently, identification is mostly approached from an inward-looking perspective (*Dumas, et al., 2013*). Blockchain technology adds another relevant perspective for evaluating high-level processes in terms of the implied strengths, weaknesses, opportunities, and threats. For example, how can a company systematically identify the most suitable processes for blockchains or the most threatened ones? Research is needed into how this perspective can be integrated into the identification phase. Because blockchains have affinity with the support of inter-organizational processes, process identification may need to encompass not only the needs of one organization, but broader known and even unknown partners (Mkrttchian, et. al, 2019).

Process discovery refers to the collection of information about the current way a process operates and its representation as an as-is process model. Currently, methods for process discovery are largely based on interviews, walkthroughs and documentation analysis, complemented with auto-mated process discovery techniques over non-encrypted event logs generated by process-aware information systems (*Aalst, Wil, 2016*). Blockchain technology defines new challenges for process discovery techniques: the

information may be fragmented and encrypted; accounts and keys can change frequently; and payload data may be stored partly on-chain and partly off-chain.

For example, how can a company discover an overall process from blockchain transactions when these might not be logically related to a process identifier? This fragmentation might require a repeated alignment of information from all relevant parties operating on the blockchain. Work on matching could represent a promising starting point to solve this problem (*Cayoglu, 2014; Euzenat and Shvaiko, 2013 and other*). There is both the risk and opportunity of conducting process mining on blockchain data. An opportunity could involve establishing trust in how a process or a prospective business partner operates, while a risk is that other parties might be able to understand operational characteristics from blockchain transactions. There are also opportunities for reverse engineering business processes, among others, from smart contracts (Mkrttchian, et. al, 2019).

Process analysis refers to obtaining insights into issues relating to the way a business process currently operates. Currently, the analysis of processes mostly builds on data that is available inside of organizations or from perceptions shared by internal and external process stakeholders (Mendling, 2018). Records of processes executed on the blockchain yield valuable information that can help to assess the case load, durations, frequencies of paths, parties involved, and correlations between unencrypted data items. These pieces of information can be used to discover processes, detect deviations, and conduct root cause analysis (*Dumas, et al., 2013*), ranging from small groups of companies to an entire industry at large. The question is which effort is required to bring the available blockchain transaction data into a format that permits such analysis. Process redesign deals with the systematic improvement of a process. Currently, approaches like redesign heuristics build on the assumption that there are recurring patterns of how a process can be improved (*Mendling, 2018*). Blockchain technology offers novel ways of improving specific business processes or resolving specific problems. For instance, instead of involving a trustee to release a payment if an agreed condition is met, a buyer and a seller of a house might agree on a smart contract instead. The question is where blockchains can be applied for optimizing existing interactions and where new interaction patterns without a trusted central party can be established, potentially drawing on insights from related research on Web service interaction (Mkrttchian, et. al, 2019).

A promising direction for developing blockchain-appropriate abstractions and heuristics may come from data-aware workflows and diagrams. Both techniques combine two primary ingredients of blockchain, namely data and process, in a holistic manner that is well-suited for top-down design of cross-organizational processes. It might also be beneficial to formulate blockchain-specific redesign heuristics that could mimic how Incoterms define standardized interactions in international trade. Specific challenges for redesign include the joint engineering of blockchain processes between all parties involved, an ongoing problem for design (Mendling, 2018). Process implementation refers to the procedure of transforming a to-be model into software components executing the digital economy process. Currently, same processes are often implemented using process-aware information systems or business process management systems inside single organizations. In this context, the question is how the involved parties can make sure that the implementation that they deploy on the blockchain supports their process as desired. Some of the challenges regarding the transformation of a process model to blockchain artifacts are discussed by (*Mendling, 2018*).

It has to be noted that choreographies have not been adopted by industry to a large extent yet. Despite this, they are especially helpful in inter-organizational settings, where it is not possible to control and monitor a complete process in a centralized fashion because of organizational borders. To verify that contracts between choreography stakeholders have been fulfilled, a trust basis, which is not under control of a particular party, needs to be established. Blockchains may serve to establish this kind of

trust between stakeholders. An important engineering challenge on the implementation level is the identification and definition of abstractions for the design of blockchain-based business process execution. Libraries and operations for engines are required, accompanied by modeling primitives and language extensions of digital economy process. . Software patterns and anti-patterns will be of good help to engineers designing blockchain-based processes. There is also a need for new approaches for quality assurance, correctness, and verification, as well as for new corresponding correctness criteria. These can build on existing notions of compliance the more, dynamic partner binding and rebinding is a challenge that requires attention (Mkrttchian, et. al, 2019).

Process participants will have to find partners, either manually or automatically on dedicated market-places using dedicated look-up services. The property of inhabiting a certain role in a process might itself be a tradable asset. For example, a supplier might auction off the role of shipper to the highest bidder as part of the process. Finally, as more and more companies use blockchain, there will be a proliferation of smart contract templates available for use. Tools for finding templates appropriate for a given style of collaboration will be essential. All these characteristics emphasize the need for specific testing and verification approaches. Execution refers to the instantiation of individual cases and their information-technological processing. Currently, such execution is facilitated by process-aware information systems or digital economy process management systems. For the actual execution of a process deployed on a blockchain following the method of (Mendling, 2018), several differences with the traditional ways exist.

During the execution of an instance, messages between participants need to be passed as blockchain transactions to the smart contract; resulting messages need to be observed from the blocks in the blockchain. Both of these can be achieved by integrating blockchain technology directly with existing enterprise systems or through the use of dedicated integration components, such as the triggers suggested by (Mendling, 2018). The main challenge here involves ensuring correctness and security, especially when monetary assets are transferred using this technology. Process monitoring refers to collecting events of process executions, displaying them in an understandable way, and triggering alerts and escalation in cases where undesired behavior is observed.

Currently, such process execution data is recorded by systems that support process execution (Mendling, 2018). *First*, we face issues in terms of data fragmentation and encryption as in the analysis phase. For example, the data on the blockchain alone will likely not be enough to monitor the process, but require integration with local off-chain data. Once such tracing in place, the global view of the process can be monitored independently by each involved party. This provides a suitable basis for continuous conformance and compliance checking and monitoring of service-level agreements. *Second*, based on monitoring data exchanged via the blockchain, it is possible to verify if a process instance meets the original process model and the contractual obligations of all involved process stakeholders. For this, blockchain technology can be exploited to store the process execution data and handoffs between process participants. Notably, this is even possible without the usage of smart contracts, i.e., in a first-generation blockchain like the one operated by digital economy.

Runtime adaptation refers to the concept of changing the process during execution. In traditional approaches, this can for instance be achieved by allowing participants in a process to change the model during its execution. Interacting partners might take a defensive stance in order to avoid certain types of adaptation. As discussed by (Mendling, 2018), blockchain can be used to enforce conformance with the model, so that participants can rely on the joint model being followed. In such a setting, adaptation is by default something to be avoided: if a participant can change the model, this could be used to gain an unfair advantage over the other participants. For instance, the rules of retrieving digital process from an escrow account could be changed or the terms of payment. In this setting, process adaptation

must strictly adhere to defined paths for it, e.g., any change to a deployed smart contract may require a transaction signed by all participants.

In contrast, the method proposed by Mendling et al. (*Mendling, 2018*) allows runtime adaptation, but assumes that relevant participants monitor the execution and react if a change is undesired. If smart contracts enforce the process, there are also problems arising in relation to evolution: new smart contracts need to be deployed to reflect changes to a new version of the process model. Porting running instances from an old version to a new one would require effective coordination mechanisms involving all participants.

There are also challenges and opportunities for digital economy process and blockchain technology beyond the classical lifecycle. We refer to the capability areas beyond the methodological support we reflected above, including strategy, governance, information technology, people, and culture. Strategic alignment refers to the active management of connections between organizational priorities and business processes, which aims at facilitating effective actions to improve business performance. Currently, various approaches to digital economy process assume that the corporate strategy is defined first and business processes are aligned with the respective strategic imperatives (*Mendling, 2018*). Blockchain technology challenges these approaches to strategic alignment. For many companies, blockchains define a potential threat to their core digital economy processes. For instance, the banking industry could see a major disintermediation based on blockchain-based payment services. Also lock-in effects might deteriorate when, for example, the banking service is not the banking network itself anymore, but only the interface to it. These developments could lead to business processes and business models being under strong influence of technological innovations outside of companies (Mkrttchian, et. al, 2019).

The digital economy process governance refers to appropriate and transparent accountability in terms of roles, responsibilities, and decision processes for different digital economy-related programs, projects, and operations. Currently, digital economy processes as a management approach builds on the explicit definition of digital economy processes management-related roles and responsibilities with a focus on the internal operations of a company. Blockchain technology might change governance towards a more externally oriented model of self-governance based on smart contracts. Research on corporate governance investigates agency problems and mechanisms to provide effective incentives for intended behavior (*Mendling, 2018*).

Smart contracts can be used to establish new governance models as exemplified by Mendling et al. (2018). It is an important question in how far this idea of Mendling can be extended towards reducing the agency problem of management discretion or eventually eliminate the need for management altogether. Furthermore, the revolutionary change suggested by Mendling, for organization shows just how disruptive this technology can be, and whether similarly radical changes could apply to digital economy processes management (*Mendling, 2018*).

Digital economy processes management-related information technology subsumes all systems that support process execution, such as process-aware information systems and digital economy process management systems. These systems typically assume central control over the process. Blockchain technology enables novel ways of process execution, but several challenges in terms of security and privacy have to be considered. While the visibility of encrypted data on a blockchain is restricted, it is up to the participants in the process to ensure that these mechanisms are used according to their confidentiality requirements. Some of these requirements are currently being investigated in the financial industry. Further challenges can be expected with the introduction of the digital economy in Russian Federation. It is also not clear, which new attack scenarios on blockchain networks might emerge. Therefore, guidelines for using private, public, or consortium-based blockchains are required.

A person in this context refers to all individuals, possibly in different roles, who engage with digital economy processes management. Currently, these are people who work as process analyst, process manager, process owner or in other process-related roles. The roles of these individuals are shaped by skills in the area of management, business analysis and requirements engineering. In this capability area, the use of blockchain technology requires extensions of their skill sets. New required skills relate to partner and contract management, software engineering and big data analysts. Also, people have to be willing to design blockchain-based collaborations within the frame of existing regulations to enable adoption. This implies that research into blockchain-specific technology acceptance is needed, extending the established technology acceptance model (*Mendling, 2018*).

Organizational culture is defined by the collective values of a group of people in an organization. Currently, digital economy processes management is discussed in relation to organizational culture from a perspective that emphasizes an affinity with clan and hierarchy culture. These cultural types are often found in the many companies that use digital economy processes management as an approach for documentation. Blockchains are likely to influence organizational culture towards a stronger emphasis on flexibility and an outward-looking perspective. In the competing values framework by Mendling et al. (2018), these aspects are associated with an adhocracy organizational culture. Furthermore, not only consequences of blockchain adoption have to be studied, but also antecedents'. These include organizational factors that facilitate early and successful adoption (*Mkrttchian, et. al, 2019*).

By itself, stored data does not generate business value, and this is true of traditional databases, data warehouses, and the new technologies for storing big data. Once the data is appropriately stored, however, it can be analyzed, which can create tremendous value. A variety of analysis technologies, approaches, and products have emerged that are especially applicable to big data, such as in-memory analytics, in-database analytics, and appliances. In our study we are using Intelligent Visualization Techniques for Big Data Analytic, or business intelligence (*Mkrttchian and Aleshina, 2017; Plotnikov, 2016; Mkrttchian, 2011; Mkrttchian, 2012 and other*).

It is helpful to recognize that the term analytics is not used consistently; it is used in at least three different yet related ways. A starting point for understanding analytics is to explore its roots. Decision support systems (DSS) in the 1970s were the first systems to support decision making. DSS came to be used as a description for an application and an academic discipline. Over time, additional decision support applications such as executive information systems, online analytical processing (OLAP), and dashboards/scorecards became popular (*Watson and Hugh, 2014*).

Descriptive analytics, such as reporting/OLAP, dashboards/scorecards, and data visualization, have been widely used for some time, and are the core applications of traditional BI. Descriptive analytics are backward looking (like a car's rear view mirror) and reveal what has occurred. One trend, however, is to include the findings from predictive analytics, such as forecasts of future sales, on dashboards/scorecards (*Watson and Hugh, 2014*).

The methods and algorithms for predictive analytics such as regression analysis, machine learning, and neural networks have existed for some time. Recently, however, software products such as SAS Enterprise Miner have made them much easier to understand and use. They have also been integrated into specific applications, such as for campaign management. Marketing is the target for many predictive analytics applications; here the goal is to better understand customers and their needs and preferences.

Some people also refer to exploratory or discovery analytics, although these are just other names for predictive analytics. When these terms are used, they normally refer to finding relationships in big data that were not previously known. The ability to analyze new data sources—that is, big data—creates additional opportunities for insights and is especially important for firms with massive amounts of

customer data. Golden path analysis is a new and interesting predictive or discovery analytics technique. It involves the analysis of large quantities of behavioral data (i.e., data associated with the activities or actions of people) to identify patterns of events or activities that foretell customer actions such as not renewing a cell phone contract, closing a checking account, or abandoning an electronic shopping cart. When a company can predict a behavior, it can intercede, perhaps with an offer, and possibly change the anticipated behavior (Watson and Hugh, 2014).

There is no formula for choosing the right platforms. However, the most important considerations include the volume, velocity, and variety of data; the applications that will use the platform; that the users are; and whether the required processing is batch or real time. Some work may require the integrated use of multiple platforms. The final choices ultimately come down to where the required work can be done at the lowest cost. For our goal is good Triple H Avatar an Avatar-based Software Platform for HHH University, Sydney, Australia.

CONCLUSION

Blockchain will fundamentally shift how we deal with transactions in general, and therefore how organizations manage their business processes within their network. Discussion of challenges in relation to the digital economy processes management lifecycle and beyond points to seven major future research directions. For some of them we expect viable insights to emerge sooner, for others later. The order loosely reflects how soon such insights might appear. The digital economy processes management and the Information Systems community have a unique opportunity to help shape this fundamental shift towards a distributed, trustworthy infrastructure to promote inter-organizational processes.

KEY TERMS AND DEFINITIONS

Audit and Policy Mechanisms: Is a section of avatar-based management techniques.

Avatar-Based Management: Is control methods and techniques introduced by V. Mkrttchian in 2018.

Blockchain: Is a growing list of records, called blocks, which are linked using cryptography. Each block contains a cryptographic hash of the previous block a timestamp, and transaction data.

Cyber Security: Is section of information security, within the framework of which the processes of formation, functioning and evolution of cyber objects are studied, to identify sources of cyber-danger formed while determining their characteristics, as well as their classification and formation of regulatory documents, implementation of security systems in future.

Machine Learning Application: Is class of methods of artificial/natural intelligence, the characteristic feature of which is not a direct solution of the problem but training in the process of applying solutions to a set of similar problems.

Maturity Models: Is a section of avatar-based management.

Predictive Analytics: Is the use of data, statistical algorithms, and machine learning techniques to identify the likelihood of future outcomes based on empirical data.

An Overview (and Criticism) of Methods to Detect Fake Content Online

Antonio Badia

University of Louisville, USA

INTRODUCTION

The Web facilitates the spread of information thanks to its interconnected nature and the ease of publishing on it; but there seems to be lately a drastic increase in content of doubtful veracity (Kumar and Shah, 2018). Given the use of the Web as a diffusion media (60% of Americans get their news from social media, according to (Allcott et al, 2017)), this has become an important issue. In the Web, it is relatively easy to produce content that maximizes dissemination (achieves ‘virality’) by using attention-calling techniques (like clickbait) that take advantage of recommendation algorithms. As a result, there is a process of ‘algorithmic amplification’ of fake content (DiResta, 2018).

This has produced alarm, as false and misleading information is reaching wide audiences and doing it faster than truthful, accurate content (Shao et alia, 2018; Hui et alia, 2018). Therefore, there is much interest in the research community (and society at large) in detecting certain forms of fake content and eliminating (or at least restricting) its diffusion.

In this chapter, we provide an overview of recent algorithmic approaches to detecting fake content. This is a very active and ongoing area of work; we will not offer a comprehensive review of all relevant research, rather offering a representative sample. The thesis of this chapter is that such research is characterized by a very narrow scope and a lack of definition of its target (i.e. what exactly is fake content?). To support this thesis, we first examine the concept and show that it is a multi-faceted, complex phenomena; hence, it is very difficult to agree on an exact definition of what constitutes falsehood. As a result, most research has focused on a narrow subset of the topic (usually called fact checking). Next, we summarize research efforts to detecting fake content, and provide a brief evaluation of the state of the art. Finally, we sketch some suggestions for future research, emphasizing that this is still an open problem and that further work will require a better approach to defining fake content and its various aspects.

We do not cover other, closely related aspects of the problem, like legal, political and criminal approaches to defining, detecting and fighting fake content. Such aspects are very interesting and relevant, but deserve a chapter of their own. Rather, we assume that technological efforts to detect false content are an important tool that can be used by these other approaches, but to do so it must evolve past current attempts.

BACKGROUND: DEFINING FAKE CONTENT

One of the most challenging aspects of the research about fake content is the difficulty of defining the concept. There is much disagreement among authors; while the idea of being ‘true’ or ‘false’ has a strong intuitive sense, there is a lack of formal definitions that are widely shared. A considerable amount of work does not formally define ‘fake’ or ‘false’ (or, equivalently, ‘true’ or ‘truth’). Thus, ad-hoc defini-

DOI: 10.4018/978-1-5225-9715-5.ch072

tions are used in many cases (Shu et al., 2017). For instance, a Stanford study on misinformation uses a set of fake content obtained by combining articles from the PolitiFact web site, the BuzzFeed website, and two previous academic articles (Allcott et al., 2019). It classifies as fake news any post from a short list of sites which are ‘well known to be providers of false information.’ To make the issue even more complicated, there are a number of related concepts (fake reviews, clickbait, rumors, hate speech, cognitive hacking) that tend to get confused (that is why this article uses the more neutral label ‘fake content’ (Tandoc et al., 2017)).

An area that has looked in depth at the problem of true or authentic information is that of Intelligence studies; this area provides a starting point for trying to define false news (Hansen, 2017). Based on this work, we can distinguish the following aspects:

- **‘Fake’ as ‘Non-Factual’:** This refers to statements describing events or facts that are considered not to be a faithful representation of what happens in the real world. Many studies implicitly use this idea; for instance, “Fake news is an article that is intentionally and verifiably false.” (Shu et al., 2017, p. 23). Note that this approach requires the existence of some ground truth that can be objectively assessed; this is easy in some cases (location of a store, hours it is open) but not so in others. Factual statements may involve several aspects:
 - Factual concrete information, that is, about a particular event or action. The falsehood usually refers to describing an event that did not happen, and denying the occurrence of an event that did happen. Most research in fake content focuses on this aspect of the issue.
 - **Factual General Information:** This refers to general or scientific knowledge. An example of this is how medical knowledge is distorted by many pseudo-scientific theories that proliferate on the Web, like anti-vaccine beliefs. Another example is climate change denial. There is a debate as to whether these platforms actively contribute to maximize the impact of this pseudo-information, due to their algorithms (DiResta, 2018).
- **‘Fake’ as ‘Incomplete/Misleading’:** For complex events or actions, an accurate and complete description may involve complex statements. A partial description presenting carefully selected aspects, with each aspect factually true, may create a false impression: “omitted facts or untold stories which, if viewed by the standard of traditional editorial guidelines, would definitely have been considered newsworthy.” (Hanson, 2017, p. 21). This is usually achieved by suppressing some relevant aspects and/or highlighting barely meaningful ones, and can be considered a falsehood in the sense that the significance or interpretation of the event or action in a larger context is completely hidden.
- **‘Fake’ as ‘Biased’:** The description is done from one perspective only, resulting in a slanted view of the event or action: “the reporting may be so one-sided as to disqualify it. It may not necessarily contain untruths, but it is done less to inform than to leave the news consumer with a certain set of emotions and, ultimately, with certain political preferences.” (Hanson, 2017, p. 21). Note that, different from the previous case, where each individual statement was truthful but the collection was not, here the individual statements (whether there is only one or several) are distorted.
- **‘Fake’ as ‘Opinion’:** This refers to non-factual information: opinion, commentary on news, and similar. This is the most ambiguous area, since it is assumed that when someone gives an opinion, the speaker is not bound to be objective. This area includes speech which is conflictive for other reasons, like hate speech; however, given its ambiguity, hate speech is usually not considered a target for fake content detection, with a few specific exceptions: in e-commerce, *fake reviews* is

a significant problem (Mukherjee et alia, 2013). While there is also research on detecting hate speech (Gröndahl et alia, 2018), it will not be covered in this article.

There are other possible classifications of fake content. For instance, (Tandoc et alia, 2017) propose a typology using 2 dimensions: the degree of facticity, and the intention to deceive. (Wardle 2017) proposes 3 dimensions: the type of content, the motivation(s) of the creator(s), and the way the content is disseminated. Another classification is based on the origin of the content:

- **Generated by a Person:** this can be further subdivided into user generated content (fake reviews, mostly) and professional generated content (fake news, when written by a group of professional writers, usually under the auspices of some organization, in order to generate and adversarial setting).
- **Generated by Machine:** This can refer to reviews or news; the distinctive feature is that they are generated by algorithm. The goal here is to extend the reach of fake content by generating a large amount of such content and spreading it widely.

An important (but orthogonal) issue is that of intentionality. Usually, a distinction between ‘misinformation’ and ‘disinformation’ is made in this context. Disinformation is taken to refer to “information which is known to be untrue or even deliberately fabricated. It is intentionally false.” while disinformation refers to situations where the source is unaware that the information is false. Note that the same statement may fall under both cases, depending on the context: “If [disinformation] is subsequently spread by someone who is unaware of its false nature, it is reduced to misinformation. (The term “fake news” seems to include both disinformation and misinformation.)” (Hansen, 2017, p. 21). This aspect is important in certain fields, for instance legal: “For purposes of this article, we define “fake news” as the online publication of intentionally or knowingly false statements of fact.” (Klein and Wueller, 2017). However, here we do not consider this issue, as most algorithmic approaches also disregard this aspect.

There are other notions closely related to ‘falsehood’ but different from it. The term “cognitive hacking” refers to the manipulating public opinion for de-stabilizing efforts like stock market manipulation, attacking media credibility, etc. It can be achieved by any of the aspects described above. Some authors argue that, while many approaches try to establish the credibility of sources, truth is different from credibility: credibility can be considered a subjective property; in communication, receiver and sender may disagree on issues of credibility (Wierzbicki, 2018). Controversial information is that for which there is a disagreement in credibility.

Finally, and even though most approaches reviewed here focus on text, fake content is not always expressed textually. The production of non-truthful content can be extended to other media: deep fakes are the equivalent of fake content in multimedia (video, audio and images).

APPROACHES TO DETECTION

There are two basic approaches to detecting fake content: human based and computational. We describe each one in turn.

Human-Based Approaches

Human-based approaches, like their name indicates, are ultimately based on a person's identification of discrepancies between what a message says and established facts ('manual fact checking'). Since this approach is labor intensive, and there is an element of individual judgment that may bias the results, this is usually a team effort. This approach has been used by Facebook, Twitter and other companies due to the limitations of current computational approaches (see below).

Human-based efforts usually depend on curated sources. There have been several projects to identify and gather collections of trustable sources. The WOT system¹ uses crowdsourcing to determine if a web site is credible. However, crowdsourcing may be manipulated using *astroturfing*, the practice of making a message appear as if originated by a 'grassroots' movement and hiding the real originator. Snopes² focuses on evaluating urban legends. Politifact³ deals with statements made by politicians and other people with authority. It uses a team of experts (journalists). Evaluations result in ratings, which are usually accompanied by detailed explanations of the rating. FactCheck.org⁴ focuses on statements by politicians and also relies on journalists. The Stanford Web Credibility Project⁵ focuses more on how users evaluate the credibility of Web resources.

Human-based approaches have severe limitations. First, the approaches used at Internet companies like Facebook are not public and therefore it is not known what guidelines the humans use or what definition of fake information is used, or how it is detected. This has led to a variety of groups claiming discrimination by the company. Second, the human approach depends on a person's judgment and this involves the risk of biased, incomplete or even inconsistent results (Lim, 2018). Finally, this approach does not scale to Internet size, and therefore is it unlikely to be a long-term solution.

Algorithmic Approaches

The problems of human-based approaches has led to interest in computational approaches. These approaches can, in turn, be divided into three broad classes: knowledge-based, diffusion-based, and content-based.

Knowledge-based approaches compare the content of a message with established ground truth collected on knowledge bases like DBpedia (Ciampaglia et al., 2105; Shi and Weninger, 2016). The main challenges to these approaches are twofold. First, they depend on the coverage of the knowledge base, which can be quite limited in certain domains. Second, it can be very difficult to detect subtle contradictions in two pieces of text (Marneffe et al., 2018).

Approaches based on diffusion are mainly applied to Web content, since in this environment it is usually possible to trace the spread of content (and sometimes its lineage, ie where it originated and how it was transmitted). It is claimed that false content disseminates in a manner different from truthful content, and hence can be detected by examining patterns of diffusion (Shao et alia, 2016; Hui et alia, 2018, Vosoughi et alia, 2018). These approaches have been successful in detecting hoaxes, fake reviews and spam (Tachini et alia, 2017; Zin et alia, 2016). However, many of them examine patterns of diffusion and therefore only help to detect fake news after they have reached many users.

Content-based approaches are usually based on Machine Learning techniques, in particular, Supervised Machine Learning. In this approach, training data (usually, collections of news articles) are described by a set of attributes or *features* and labeled (classified as 'fake' or 'real'). A Machine Learning algorithm is fed the training data and it attempts to learn a model, which identifies patterns in the data connecting the features with the labels. The model is then fed new, unlabeled news articles and is able to determine whether they are 'fake' or 'real'. The set of features used varies per approach, but it usually includes

lexical features (the presence or absence of certain words, the style in which a document is written, number of spelling mistakes, presence or absence of quotes, etc.), although sometimes additional features (information about the source) are also used. For instance, for clickbait detection, it is common to include the token similarity between title and text and the existence of certain Part Of Speech (POS) patterns (Chen, Conroy and Rubin, 2015a). Sometimes, specific patterns are found to work in certain domains, like the use of satirical language in fake news production (Chen, Conroy and Rubin, 2016).

Some computational approaches have achieved good results, albeit in limited domains. For instance, clickbait detection has been shown to be a bit easier than fake content detection, thanks the characteristics of clickbait: an attention-gathering title or headline that has a weak connection with the content of the article (Chen, Conroy and Rubin, 2015b) plus repetitions in the content (Horne and Adali, 2017).

Algorithmic approaches are hard to evaluate because there are not widely recognized benchmarks for fake news detection, and not widely agreed-upon method to determine accuracy; as a result, each group of researchers uses their own dataset.

Evaluation

Algorithmic approaches to fake news detection have some common characteristics. First, they limit themselves to dealing with factual (concrete) information and do not deal with more complex scenarios. In particular, misleading or biased information is beyond the scope of most approaches. Second, many approaches do not attempt to actually check the content of the messages or text they deal with: they instead rely on diffusion patterns (when dealing with messages on social networks (Shao et al., 2016)) or on lexical and syntactic features of the text (Yang and Nenkova, 2017). Third, no approach has a clear, explicit definition of what being fake is. In this regard, it is important to point out that Machine Learning approaches do not have an explicit definition of fake, but do use an implicit definition: such a characterization comes from their labeled dataset. In essence, the set of messages or texts that are marked as ‘fake’ constitute an implicit definition.

As a result of these characteristics, even state-of-the-art algorithms have serious limitations: those based on network dissemination only apply to social media, and determine truthfulness a posteriori, after the message has spread, thereby not being useful for prevention. Those based on content work better when the content is limited to a certain style, like clickbait, that provide strong structural clues. All computational approaches are very hard to evaluate as there are no widely adopted benchmarks. On top of the current limited effectiveness, some new research has shown that such tools are not difficult to fool (Grondahl et al. 2018).

FUTURE RESEARCH DIRECTIONS

As should be clear from this overview, detecting fake content is an open problem. There is no wide agreement on what constitutes the target concept, which in turn makes it very difficult to create widely shared and used benchmarks. In particular, for approaches that depend on deep learning, the creation of labeled data sets for training is highly problematic. It is known, from past experience, that extreme care is needed when creating training sets, since most algorithms will pick any bias, intentional or unintentional, in the training data (O’Neil, 2014; Noble, 2018). The importance of this problem is reflected on the nascent field of Algorithmic Fairness (Sun et alia, 2018). Thus, it is urgent that researchers agree on an acceptable definition of what is ‘fake content’ and that shareable benchmarks are developed. Also,

labeled datasets for training would be very desirable for approaches based on Supervised Machine Learning. While a few already exist, they have not gained widespread usage (Vlachos and Riedel, 2014).

Some authors have argued that the problem has no algorithmic solution and that social, legal and organizational approaches are needed. While it is clear that fake content does require a concerned effort on all these fronts, computational approaches are absolutely needed in order to push back against the Internet scale of the problem. This is not to say that other approaches cannot help; for instance, finding a way to reduce the incentives (monetary and otherwise) to produce fake news would go a long way towards solving the problem. At the same time, any said solutions must be developed with care; simply leaving control of what is and is not shareable (what constitutes fake content, spam, hate speech and so on) to a few companies may devolve into censorship and biases. Thus, this is an issue that should involve society at large.

CONCLUSION

Fake content generation and distribution on the Web is a very important problem, perhaps the top problem in the Web nowadays due to its repercussions. In spite of this, it has been only recently that researchers and institutions have started spending a substantial amount of effort to combat it. The problem is still open and is the subject of very active research.

Both human-based and computation-based approaches have been proposed. Unfortunately, both types have significant drawbacks. On the computational side, the lack of agreement on exactly what constitutes false content has resulted in a lack of standardized benchmarks to evaluate research, and in difficulty to develop labeled data for Supervised Machine Learning approaches.

One important aspect is the role that social networks themselves play in the diffusion of false content. As seen above, a considerable body of research argues that this content disseminates faster and wider than truthful content. Reluctance to control content has also make the situation more problematic.

In the future, we can expect to see more Machine Learning models being developed, as more and better labeled datasets become available, and more features are included. We can also expect to see other solutions besides purely technical ones; the study by Hansen “suggests to focus on the build-up of greater cognitive resilience, that is, the ability to withstand pressure from various ideas spread, for instance, through disinformation.” (Hansen, 2017, p. 35) The idea is to make individuals immune to contagion by making them not believe such news: “In essence, it will allow for the free flow of information, including from Russian state-controlled media, but it will establish a cognitive ‘firewall’, which prevents the disinformation from taking root and being internalized by members of the target audience.” (Hansen, 2017, p. 35) This is not a technical, even business-based, solution: the firewall should work at the institutional and personal level. That is, the whole population should be involved; this is to be achieved by education -providing everyone with media literacy (Hanson, 2017), the ability to examine critically pieces of information and tell fake news from real ones.

KEY TERMS AND DEFINITIONS

5

Clickbait: Web article with an attention-gathering headline designed to make users click on the link, but with content rarely connected to the headline at all.

Crowdsourcing: The practice of hiring a (large) group of people (the ‘crowd’) to accomplish a certain task, usually a repetitive task that does not require special training but that must be carried out over a large amount of data.

Disinformation: False content that is deliberately fabricated and distributed.

Fake News: False content that tries to appear as coming from a traditional news media outlet.

Fake Reviews: Product review produced with the goal of artificially improving (or damaging) the ratings of the product.

Hate Speech: Speech that attacks a group (or, sometimes, a person) based on categories like race, sex, religion, origin or disability. Its goal is to incite prejudice and spread bigoted views.

Misinformation: False content that is the product of error (i.e., whose originator or distributor may not be aware that the content is not truthful).

INTRODUCTION

E-marketers are on the constant lookout for ways to generate visitor traffic to their e-commerce sites in a cost-effective manner. Search Engine Optimised (SEO) page rankings, paid-search, keyword bidding, *cost-per-mille* display advertising (CPM) and *cost-per-click* banner advertising (CPC) are some of the different ways to attract user traffic; for a fee. With the advent of *Affiliate Marketing* (AM) businesses around the globe found a new way to generate visitor traffic at a relatively low cost, using a network of affiliates (Brear & Barnes, 2008; Norouzi, 2017). Nevertheless, increasing criminal activities on Internet has made CPM and CPC advertising models prone to large scale fraud activities, such as *click-fraud* (Edelman, 2015). In this backdrop, cost-per-acquisition (CPA) appeared as the silver bullet against AM fraud, as under CPA e-commerce sites do not pay for *clicks* or for page visits anymore. The affiliates are instead rewarded only for monetary outcomes (Hu, Shin, & Tang, 2013). Though CPA is considered the safest and most cost-efficient visitor traffic generation model for Small-to-Medium Enterprises (SME), the discovery of *cookie stuffing* fraud shows that it is not the silver bullet that it was thought to be. Though at a much lesser degree, some fraudulent activities have been recently discovered (Amarasekara, 2017; Chachra, Savage, & Voelker, 2015; Edelman & Brandi, 2015).

During this research an AM strategy of a current practitioner was examined. Two datasets of AM-generated web traffic data were analysed to detect any possible fraudulent patterns. These two datasets were separately generated by two different Affiliate Marketing Networks (AMN) that managed AM services for the same practitioner at two different periods of time. A test environment was developed, named AMNSTE (Amarasekara & Mathrani, 2016), which can simulate the complete set of processes that underlie web-traffic generation within a real-world AM network, using the same underlying technologies. AMNSTE consists of multiple virtual servers within different web domains. They are connected by virtual switches and routers that allow inter-domain routing. While AMNSTE has the ability to add new domains and additional servers, a minimum test configuration comprises of three web domains, each representing one of the three stakeholders in AM: Advertiser (e-commerce site), the AMN (tracking service provider), and at least one Affiliate website. Each of the three domains comprises a web server to host the website or web-services and a database server to save transaction and tracking data. Fraudulent

DOI: 10.4018/978-1-5225-9715-5.ch073

actions discovered within datasets were tested through simulations on AMNSTE, and multiple fraudulent methods were discovered to execute some of the currently known frauds. AMNSTE also allowed the authors to discover newer vulnerabilities that can be used by fraudsters in future, to defraud AM networks. The solutions proposed here were tested on AMNSTE for efficacy and utility.

This paper provides an insight in to how cybercrime is effecting e-commerce activities by endangering one of the most affordable and cost-effective traffic generation models available to SMEs. The paper first introduces the reader to the topic of Affiliate Marketing, and the underlying tracking technology based on the HTTP cookie. Then, it provides a technical perspective to the frauds that are currently known such as *Cookie stuffing* by explaining how those frauds are accomplished. It then describes new vulnerabilities that have been discovered by the authors during their current research project, which could be exploited by fraudsters in future. Next, the authors propose solutions on how to mitigate the risks, which would enable e-commerce practitioners to implement new solutions or re-examine their existing security strategies. Finally, the conclusions and future research directions are discussed that could make the tracking system more robust and reliable, in order to sustain this cost-efficient and affordable marketing model.

BACKGROUND

Affiliates are independent websites who already have a large following of visitor traffic, who might belong to the potential target market of some product advertisers. Affiliate marketing model uses a network of such affiliates, who will promote the advertiser's website, usually by displaying a banner advertisement. Figure 1 provides a logical view of the AM process, starting from a visitor's click on a banner advertisement at an affiliate's website to the completion of a purchase action. The sequence of the processes involved are numbered in the diagram. When a user views an affiliate website (process 1) and clicks an advertisement link (process 2) the "Click Pixel" embedded in the webpage causes the tracking server to create a record of the "click" action in the database (process 3). The tracking server then sends a cookie to the browser with a unique identifier that refers to this specific click. It also sends a redirect response to the browser, targeted at the advertiser's e-commerce site (process 4). The visitor then browses the e-commerce site and makes a purchase decision (process 5). The process 6 is abbreviated as "AN Res. Rq.", which stands for "Affiliate Marketing Network resource request", which refers to the "Conversion Pixel" embedded in the payment confirmation page sent by the e-commerce serve. In the background without any visible clue to the user the *Conversion Pixel* causes the user's browser to send a resource request to the tracking server with the information such as the Invoice Identifier, total purchase price, etc. as parameters of the resource request. As every HTTP request to the web server is accompanied by the cookies that the server has set previously, in this case during the click-tracking process numbered 3, the tracking server records the sales conversion details against the click-tracking data in the database. The *Click Pixel* and *Conversion Pixel* are small pieces of JavaScript code that are embedded in those webpages that provide user-specific information to the tracking server. The tracking server, while being invisible to the user, keeps track of all processes and traffic movements with the help of *tracking-cookies*. Next, how the above cross-domain tracking systems are used by different marketing models are discussed.

Figure 1. Logical view of an affiliate marketing process

Affiliate-Driven E-Marketing Strategies

Different advertising models yield different levels of visitor interactions and commitments, therefore different levels of Return on Investment (ROI) for the e-marketers. For example, CPM and *paid search* models do not guarantee any *visitors* to the e-commerce site as affiliates are paid simply for displaying the advertisement to the site-visitor; the visitor might neither click the advertisement nor even see the advertisement. Only about 1% of site visitors actually go on to click on a banner advertisement (Benediktova & Nevosad, 2008). But CPC model requires more visitor interaction, as an affiliate earns a fee only if the visitor in fact clicks on the advertisement and thereby arrives at the e-commerce site. Though there is no guarantee that a visitor may buy a product, the affiliate is nevertheless paid a fee, for the visitor-traffic. In contrary, CPA model is becoming increasingly popular among e-marketers, as affiliates are only paid for successful monetary outcomes, not for clicks or displays, thus guaranteeing ROI for the e-marketer. Therefore, the cost of each advertising model differs greatly from mere tenth of a cent for display advertising, to 5-10% of the sale value as a commission in case of CPA (Faou, et al., 2016).

Advertisers can either monitor and manage their own network of affiliates by themselves or subscribe to a third-party AMN.

HTTP-Cookies Driving the Tracking Technology

HTTP cookies have been used to maintain state in web applications that are inherently stateless. Though maintaining state during browsing sessions and during subsequent visits to the same websites enhances the user-experience, tracking user activities that does not directly contribute to the enrichment of user experiences is much frowned upon by most users (Hoofnagle, Urban, & Li, 2012). User activity on the internet is tracked for many reasons and by different parties: Some reasons for tracking are directly beneficial to the internet user, such as remembering user-preferences such as language, currency, shopping cart items, login etc., while some other reasons are for the benefit of the web-sites and e-commerce sites to gather additional customer demographics. Such additional visitor specific information help enterprises with their targeted marketing strategies. E-commerce sites also track locations of users and IP addresses during transactions for enhanced security but they also add to customer demographics used for business

analytics purposes. The above reasons for tracking directly relate to the interaction between a website and a visitor to that site, and is limited to tracking a user within a single web domain.

Some services and their underlying technologies that are used widely in e-commerce activities on the internet such as AMNs and other performance marketing models require a reliable tracking technology across multiple domains, in an inherently stateless ecosystem. This type of tracking is a technological necessity, invisible to the visitor and the website, and is not detrimental to the privacy of users, as no personally identifiable data is used in such scenarios. HTTP cookies have been used for such cross-domain tracking (Kristol, 2001), though newer technologies such as *local storage* offered by HTML5 and *ETags* could enhance the reliability of the HTTP cookie based tracking process (Ayenson, Wambach, Soltani, Good, & Hoofnagle, 2011; Soltani, Canty, Mayo, Thomas, & Hoofnagle, 2010).

But search engines and business analytic solution providers such as Google Analytics need to track activity over multiple sites and over longer periods. User-activity tracking data contained in HTTP cookies are combined with personally identifiable data collected through user accounts maintained by the above service providers and social media accounts to create comprehensive customer profiles that are used for online marketing strategies (Baumann, Haupt, Gebert, & Lessmann, 2018). Recent privacy breaches involving Cambridge Analytica (Richterich, 2018) and Facebook are examples of more serious violations of privacy of Internet users. Apart from that, user-tracking is also undertaken by state agencies, departments and other law enforcement agencies to monitor terrorist activities and to counter spy-activities to maintain national security. This category of user-tracking is beyond the scope of this chapter and is not discussed here.

HTTP Cookies have *properties* associated with them. These properties are set by the web server, when the cookie is created, and those properties decide the behaviour of the cookie. *Secure* property ensures that the cookies are sent only on an encrypted HTTPS connection, while *HTTPOnly* property makes a cookie content only accessible to the server but not to the JavaScript code on the browser. Another important property is *Expires* property that determines the lifespan of the cookie. *Domain* and *path* properties restrict if the cookie is sent with requests of the sub domains and resources from specific file paths. The browser returns the cookie only to the hosts of the same domain that set the cookie (HTTP cookies, 2018). If the cookie belongs to the same domain as the web page, such cookies are called *first-party* cookies. If the cookie belongs to a different domain than the web page, then it is a *third-party* cookie. Third-party cookies are usually placed by business analytics services or advertising service providers (Eckersley, 2010; Hoofnagle, Urban, & Li, 2012). Though a web page would usually contain links to resources that reside within the same domain and same server, third-party web advertising companies and business analytic service providers might include a resource such as an image to be delivered from their servers, so that a cookie from their domain can give access to the user's browsing behaviour (Libert, 2015). Browsers by default allow third-party cookies to be received, but it can be a security risk (Kristol, 2001).

Click-Tracking vs. Conversion-Tracking

Click-advertising or display-advertising models such as CPC or CPM are traffic generation models that pay affiliates agreed sums of money for displaying advertisements or when a visitor clicks on an advertisement, immaterial of a successful monetary outcome such as a sale. Therefore above advertising methods do not need to track ongoing interactions of visitors with e-commerce site. The initial action of displaying or clicking is recorded on a tracking server.

Under performance advertising model such as CPA, where only monetary outcomes yield a benefit to the affiliate, the tracking process comprises of two separate actions. The click-tracking records the click action first. A *conversion-pixel* embedded in the payment confirmation page of the e-commerce site, causes the visitor's browser to initiate a conversion-tracking action. After recording each conversion, the conversion tracking process looks up the click-tracking database for a corresponding *click-record*, with the same affiliate identifier and advertiser identifier.

A conversion tracking action without an accompanying tracking-cookie (when HTTP cookies are used for tracking) or without valid affiliate identifier are considered as direct sales, which are a result of the customer having come to e-commerce site directly by typing the URL in to the browser, or through organic search. In this case no affiliate payments are made, as no affiliate has been involved in that sale.

Click-Pixel and Conversion-Pixel

As a small piece of HTML or JavaScript code *click-pixels* are embedded in the web pages of affiliates, usually as a URL of an embedded banner advertisement. Some affiliates use such a click-pixel on e-mails sent to customers. Each affiliate is provided with a unique click-pixel that contains a URL to the tracking server with a unique identifier for each affiliate, passed as a parameter. A click-pixel causes the tracking server to record a click-tracking action identifying the affiliate and places a HTTP cookie in the user's browser. Click-pixels are usually implemented as a graphic image of a banner advertisement or as a hyperlink in a text advertisement.

A Conversion-pixel is embedded as an HTTP image element or invisibly as an HTML iframe element on the payment confirmation page. This causes each successful purchase by an e-commerce site visitor to be recorded on the tracking database. The tracking URL of the conversion-pixel can contain information such as the total price, transaction identifier, etc., and the HTTP cookie that was placed during the click-tracking process on the user's browser will identify the affiliate who promoted the visit.

Pixels can be embedded in any webpage that need to be tracked with specific outcomes, by passing relevant information that need to be tracked as parameters of the tracking URL. Usually a combination of an HTML based and a JavaScript based pixel is used, as JavaScript based pixel can use powerful client-side scripting capabilities to offer additional robustness to the tracking process.

CLICK FRAUDS AND CONVERSION FRAUDS

Edelman and Brandi (2015) have discussed some fraud scenarios such as cookie stuffing and typo-squatting. Chachra et al. (2015) and Snyder and Kanich (2016) have quantified the fraud prevalence within AM. The litigation against Shawn Hogan by e-bay in 2013 for AM fraud of over 15 million US dollars indicate the volume of some AM fraud (Edelman, 2015).

What Amounts to a Fraud Action?

Advertisers expect affiliates to be active participants in the process of promoting and influencing a visitor's decision to visit one or more e-commerce sites of advertisers, for which affiliates are paid a fee or a commission. Usually this happens by displaying banner advertisements on affiliates' websites and causing or motivating the visitors to click them to arrive at the e-commerce site. Any attempt to claim

the fee or commission, without participating or contributing to the decision or motivation of a visitor to the e-commerce site of an advertiser is therefore a fraud.

These frauds depend on the ability of a rogue affiliate to insert a click- or conversion-record in to the tracking database. This can be undertaken in two different ways:

1. By following and adhering to the intended underlying technology

Fraudulent action within this category, do not manipulate tracking records in the server or the technical aspects of the tracking process itself, directly. It is involved in simulating a *click* action of a visitor on an advertisement banner, manually or programmatically, and letting the natural cause of actions and underlying technology to complete the process of the fraud activity.

2. By foregoing the tracking process and manipulating the tracking data on server

This does not refer to usual server-hacking activity, as a hacker who gains access to a server in an illegitimate manner can cause multitude of damaging activities that are not discussed in this chapter. The verity of activities discussed under method refers to accessing the tracking server's publicly exposed service URLs by external parties or internally accessible interfaces by internal staff to manipulate tracking data. The externally accessible public URLs are meant for the interaction with automated tracking process, while internal access is meant for maintenance activities for the internal staff.

How this can be accomplished is discussed further below under each fraud description.

Cookie Stuffing

Cookie stuffing is the most widely known HTTP cookie-based tracking fraud that has been mentioned in previous research studies. As affiliate websites are usually special interest websites which are popular among specific interest groups, and usually have a large following, too many advertisements can affect the credibility and seriousness of such websites. A rogue affiliate can maintain a website free of advertisements, thus appear serious and credible, while causing the browser of each visitor to receive tracking-cookies from one or more advertisers, through an automated process of simulating *clicks* even when the visitor has not clicked on any advertisement banner. Each of these cookies will earn the rogue affiliate a commission, if the visitor makes any commercial transactions at any of those e-commerce sites. The visitor will be completely unaware of the background processes and receiving of cookies.

Using AMNSTE, it was possible to execute this fraud in multiple different ways. HTML code that requests a resource from the server, such as an image, icon, JavaScript or CSS file, where the source property is set to a tracking URL of a server causes the tracking server to record a *click* in its database and send a cookie containing the affiliate's identifier to the browser. The same result was also accomplished by using a CSS file, where for instance, the background image was defined by CSS code, with the image URL set to a tracking server URL. A rogue affiliate can maximise his profits by embedding numerous such elements, where each element is directed at a different tracking URL, thus stuffing cookies of many different advertisers. This caused the browser to send resource requests to each of the tracking servers, while the affiliate's web page is loaded, and in return the browser received cookies containing the rogue affiliate's identifier from each of those advertisers, denoting that the request originated from affiliate's website. Any future purchases made by the unsuspecting visitor at any of those advertisers' e-commerce sites would earn a commission for the affiliate.

This type of cookie stuffing can earn large profits for a rogue affiliate in some instances. For example, if the affiliate site is a travel blog about travelling around in New Zealand, it is highly likely that many visitors to the travel blog site might be planning a visit to New Zealand at some point in time, in future. The affiliate would stuff as many cookies from each hotel chain, car rental companies, airlines and tourism related service providers, as it is likely that the visitor to the affiliate's travel blog might visit some of those e-commerce sites to book a product or service. At such time, the previously stuffed cookie will identify the rogue affiliate as the referrer. This allows a rogue affiliate to cash in large amounts of commission money from multiple advertisers by using one site visitor.

Load-Time Click

This fraud is similar to cookie stuffing, but instead of static HTML or CSS code this fraud uses JavaScript code to dynamically simulate *click* actions of a user. An affiliate can present a webpage free of any third-party advertisements to the visitor, but without visitor's intervention simulate *click* actions on as many advertisements at will during the load event of the webpage. This fraud differs from cookie stuffing as Cross Origin Resource Sharing (CORS) restriction restricts browsers from accepting HTTP cookies in response to JavaScript code, hence can be used for CPC to emulate multiple banner clicks. But, the above restriction is only a client-side implementation, therefore the client computer still receives the cookie, which might still pose a threat similar to cookie-stuffing.

Conversion Stealing

The authors found conversion stealing to be the most serious fraud that affect advertiser revenue, in a previous study (Amarasekara & Mathrani, 2016). This fraud can be carried out as an internally or externally executed fraud, with internally executed fraud being the most damaging to the advertisers. The methods and complexity differ with internal and external threats. The aim of this fraud is to recognise the transactions that are direct sales, and attribute them to a rogue affiliate within the tracking database. This fraud affects mainly performance marketing models such as CPA, which depend on successful monetary outcomes unlike CPM or CPA models that are only concerned with display or click actions, not purchase outcomes. When executed as an internal fraud, a fraudster can create an automated process that queries the transaction database for direct sales and choose as many of them depending on applied criteria, such as specific number of highest valued transactions (or all, if one is too greedy) and insert new tracking records with those information in to the tracking database. New tracking records can be inserted using Web Application Programming Interfaces (WebAPI) provided by AM Networks for manual maintenance and update purposes or the fraudster can use externally accessible conversion-tracking web services URL. Such fraudulent records can evade detection even in case of many reconcile applications, as the newly inserted tracking records do refer to actual existing transactions, for which no commissions have been previously paid to any affiliate. Even a contract web developer without ongoing access rights to an internal system can implement this kind of an automated process during a one-time assignment that earns a regular monthly commission income for many years to come.

An external fraudster will need to find data parameters often through brute force or with trial and error guess work. Creating a single genuine transaction by the fraudster will reveal a transaction identifier that gives the clue to genuine transactions identifiers that can be used for forgery, as many systems generate transaction identifiers in sequence.

Conversion stealing does not have to happen in real-time with each conversion, but an automated process can do the data mining on transaction databases and assign selected transactions to the rogue affiliate, before the next payment cycle.

Conversion Faking

This fraud is another variation of conversion stealing, but in contrary, does not attempt to insert authentic transaction data in to the tracking database. Therefore, this fraud does not require the fraudster to have application-level access rights to the system or use an automated process within AM Network to insert the conversion records to the tracking database as conversion stealing does. This fraud can be carried out by any rogue affiliate. The success of this fraud depends largely on the security precautions implemented by the AM practitioner. If an AM practitioner depends completely on the security framework of the AM network to prevent fraud, and to filter and eliminate all fraudulent records, without implementing a transaction reconcile process on the AM practitioner's side, *conversion faking* can be highly successful for the fraudsters. In such case, a fraudster would guess transaction identifiers or invoice totals and use these information as URL parameters of the conversion-pixel, which can be found by examining the HTML/JavaScript code on confirmation page, after one successful transaction. This fraud can also be carried out programmatically, or typing the URL of the *conversion pixel* together with the required parameters manually in to a browser's URL field or embedding a hyperlink on a webpage under the control of the rogue affiliate.

Conversion Hijacking

This is a similar fraud that happens in real-time as the transaction. This is carried out externally unlike *conversion stealing*, as this fraud does not need access to the transaction databases. Adware, malicious browser plugins or similar malicious software that has infected a visitor's computer can sniff online activity, and trigger the corresponding *click-pixel* code just before the purchase (Edelman & Brandi, 2015). This will cause a cookie to be placed in the visitor's computer and the commission to be assigned to the rogue affiliate identified in the cookie.

Multiple Redirect Fraud

The *Referrer* field of the HTTP request headers reveal the last visited webpage of a visitor. Rogue affiliates cover their footprints by using multiple redirects over websites that contain legitimate content to conceal the origins of fraudulently generated web traffic (Chachra, Savage, & Voelker, 2015; Snyder & Kanich, 2016; Vacha, Saikat, & Yin, 2013). This can be used in conjunction with the other frauds mentioned above to make detection of frauds more difficult.

Typo-Squatting

Some of the frauds such as typo-squatting and keyword-bidding are considered a fraud by some advertisers, while others consider it legitimate. This depends on the advertiser's contractual agreements and different e-marketing strategies they may have used. Typo-squatting is when an affiliate acquires domain names that are very similar to an advertiser's domain (Edelman & Brandi, 2015). By squatting on similar sounding fake URLs, the affiliate captures the traffic of visitors who either mistypes the advertisers

name or types a confusingly similar name. After capturing the visitor, the affiliate can either redirect to the intended advertiser with a cookie to identify the affiliate and thereby earning the commission or forward to a website of a competitor for higher reward.

However, other non-technology based frauds too can incur heavy losses by using simple deceitful actions like temporarily occupying bookings. On most e-commerce sites, for example at a hotel or a car rental company affiliates can themselves book a car or a room a few months in advance and earn a hefty commission before eventually cancelling their booking after a few months. The rogue affiliate squats on bookings which they have no intention of honouring. Since many advertisers pay the commission at the end of the month following the purchase, the undeserving affiliate would be paid a commission not rightfully earned.

Non-Technology Based Fraud

Even non-tech savvy rogue affiliates can still inflict financial losses through conventional fraud methods that are used in other scenarios. For example, most reservation sites allow goods or services to be reserved many months in advance. Rogue affiliates can make an authentic reservation few months ahead of time, by themselves and thereby earn a hefty commission, and cancel the reservation later. Under CPC and CPM marketing models, *click-factories* of manual clicking of advertisements and using proxy servers to hide IP addresses of origin have been widely discussed in previous research. Credit card fraud such as using stolen credit cards to make reservations also fall under non-technology based frauds that are not covered in this paper.

MANAGING FRAUDS AND VULNERABILITIES

There is no one single action that can eliminate all the frauds discussed above, as frauds are numerous and the way they are executed are accordingly numerous. The different actions that we discuss below can be combined to create an effective solution to combat fraud scenarios. All conversion records, that do not have an accompanying tracking cookie indicate direct customers, an organic search traffic or a visitor traffic generated through non-AM method. Therefore no commissions are paid on behalf of those sales, and they need to be filtered out.

AM practitioners who have an in-house implementation of AM strategy, can implement the solutions proposed in this paper, as they manage the tracking data as well as e-commerce transaction data. AMNs who provide technology for AM practitioners are entrusted to detect and filter out all fraudulently generated visitor traffic and to provide the AM practitioners with an authentic set of records with legitimate traffic generation data, ready for commission payment. Some of the most important techniques that are presented in this chapter, require access to e-commerce transaction data which are not available to the AMN.

Reconcile Records

The next single most important step, is to reconcile *conversion-tracking* data with the backend transactional database of online sales. In an in-house tracking network, both tracking database and online sales transaction database are located within the private internal network, therefore a reconcile process can be integrated between tracking database and online sales transaction database. In a third-party AMN

tracking scenario, most AMNs provide Web API access to the tracking databases located in the AMN network. Web API access allow direct communication between servers, even when they are located in different domains, to securely connect and undertake CRUD (Create, Read, Update & Delete) activity. During reconcile process, the transaction identifier, transaction amount and date & time field of each conversion record should match a single online sales transaction in the transaction database. The first *filtering* process is rather easy and straightforward as it separates conversions forged by fraudsters with imaginary transaction IDs and total prices, that have been guessed. Next few steps can further filter out fraud action, and these can be carried out in a specific order, that would yield maximum benefit, depending on the setup of individual systems.

Check “Referrer” Field

Conversion pixel is placed in the payment confirmation page of the e-commerce site. Therefore, any conversion record that carries a different page URL or an empty *referrer* field, is a fraud, that has to be filtered out. Similarly, *click pixel* is placed in affiliate’s landing page. Advertisers need to maintain a record of all the pre-authorised landing page URLs of the affiliates. Click records with *referrer* fields that are either empty or contain unauthorised URLs should be rejected.

Audit Manual Entries in Tracking Database

Web API access provided by AMNs, discussed above is used to update specific fields of tracking records during the reconcile process; ex: toggle the *pending* status to *reconciled* or *paid* or *cancelled* statuses. Usually, new entries should not be added manually, as adding click- or conversion-tracking entries happen automatically, through the tracking process, using click- and conversion-pixels embedded in the web pages. *Conversion stealing* usually does not happen in *real-time*, hence, two different processes can be undertaken to detect this fraud.

Firstly, checking for addition of new tracking records using Web APIs should be audited, which are tell-tale signs of such tampering. Secondly, an automated process should compare the timestamp of each *conversion tracking* entry with the timestamp of the actual transaction. A large time difference points at a possible *conversion stealing*.

Crawl Affiliate Landing Pages

As part of regular maintenance activity, an automated process can be scheduled to crawl each authorised landing page of each affiliate. If the crawler receives any cookies during the crawl process, it indicates *cookie stuffing* fraud, as the crawler does not trigger any click actions. Some tech-savvy fraudsters are known to have implemented code in their landing pages, to recognise such crawlers and serve a *clean page* instead of the usual fraudulent page, thereby evading detection (Chachra, 2015). We need to be a step ahead of such fraudsters by concealing the identity of the crawler, by dynamically changing the *user-agent* and *referrer* fields of the HTTP request and hiding IP address using proxy servers and VPNs, etc.

Use of Buffer Tables

All online transaction data should be directed to a *buffer* table in the database, without exposing the internal transaction-related tables. For example, reservation data is entered in to *Reservation Buffer* table, assigning a unique reservation identifier, and the same record is mapped to an entry in the internal *Reservation Table* with a different reservation identifier. Within the complete internal system, the specific reservation record will be linked to the internal identifier in the *Reservation Table* while all actors external to the system, such as customers, front-line staff etc. refer to the specific reservation record with the Identifier generated by reservation buffer table. Same can be done using a *Payment Buffer* table and an internal *Payment Table*. Our research recognised attempts by external parties and in once occasion, by an internal staff of the advertiser who entered forged *conversion* records to the tracking database, but using the reservation identifier allocated by the *Reservation Buffer* table. During the reconcile process, such *conversion* entries get rejected, as the records get reconciled against the internal reservation identifier.

Audit Visitor Logs

Web server log or custom developed visitor logging features can reveal some irregular patterns that point at possible fraud attempts. For example, the web based reservation system of the AM practitioner that was examined by the authors had the facility for a customer to recall an active reservation made by the customer by entering the transaction code. This allowed the customer to view and modify a reservation. Our audit of webserver logs of the AM practitioner revealed regular brute-force attacks to extract authentic transaction identifiers from the system. Large number of repeated attempts, from the same IP address, within milliseconds apart pointed at automated processes, while some within a few dozens of seconds pointed at possible manual brute-force attacks.

FUTURE RESEARCH DIRECTIONS

As with every other IT security effort, researchers need to stay ahead of the attackers and fraudsters who also continue to refine their tactics to evade detection. Ongoing research activities of the authors are directed at hardening and making the HTTP cookie based tracking system more robust by complimenting HTTP cookie based tracking technologies with client-side technologies such as *HTML5 Local storage*, *ETags*, etc. (Laperdrix, Rudametkin, & Baudry, 2016; Snyder, Ansari, Taylor, & Kanich, 2016). The effectiveness of using a mix of stateful and stateless tracking methods need to be investigated (Englehardt & Narayanan, 2016).

The software industry has an opportunity to invest in research and development of standardised solutions to cater to the e-marketing platforms that would result in continuous and timely application of security measures to counter evolving vulnerabilities.

CONCLUSION

Access to the internet is expanding throughout the globe and more people spend more time connected through multitude of devices, for daily needs. Products are purchased and services are subscribed to, beyond physical and geographical boundaries that allows even small entrepreneurs in developing

countries and developed countries alike, to reach customers across the globe. CPA method of affiliate marketing model allows SMEs to reach the target markets without the technical expertise required for many other forms of e-marketing technologies. It also shifts the marketing paradigm of the need to spend an advertising budget before reaching out to potential customers; under CPA advertising cost for traffic generation is paid by profits of the sale (Norouzi, 2017). Therefore, the survival and development of this cost-efficient technology depends on continuous research and development of solutions to mitigate fraud and vulnerabilities, and implementation thereof by the industry.

KEY TERMS AND DEFINITIONS

AMNSTE: An acronym for a research tool developed by the authors during the on-going research project, Affiliate Marketing Network Simulation and Testing Environment, which has been previously published.

Conversion: A visitor to an e-commerce site completes a desired monetary transaction such as buying product or signing up for a service or a membership or whatever expectations an e-commerce site is intended to achieve by having visitors to the e-commerce site. A visit converts to a monetary outcome.

CPA: Cost-per-acquisition advertising model pays affiliates only for visitor traffic that generated an income for the e-commerce site.

CPC: Cost-per-click advertising model pays affiliates for each visitor that was re-directed to the advertiser's e-commerce site, immaterial of the financial outcome; even if the visitor does not buy any products.

CPM: Cost-per-mille advertising model pays affiliates for simply displaying an advertisement of the e-commerce site to a visitor to the affiliate's website. This model requires least interaction by a visitor.

ETag: Entity Tag is a server-side identifier assigned to content for cache-control. The browser caches and sends the ETag on subsequent web requests, which allows the server to send the resource only if the server version has changed. ETag can also be used to track users uniquely, online.

HTML5: Version 5 of hypertext mark-up language which was released in October 2014 added major improvements and features such as ability to handle multimedia and graphic features natively, and a web storage framework that can store data similar to previous usage of cookies.

HTTP Cookie: Due to security reasons, websites visited by an Internet user are not allowed to access the internal storage of the visitor's computer, such as the hard disk. The only way to store a small amount of data such as visitor's preferences, which is individual to each visitor is to store it within the browser's storage, as plain text. Such storage is called a cookie, which was in earlier browsers a text-based file on the visitor's computer. But now each browser decide how it stores. Though a browser may have many hundreds of cookies, each saved by a different website, each website can only access the cookie that it has placed, but not the cookies placed by another website.

Stateful Tracking: Using identifiable information stored in a user's local computer, such as an HTTP cookie to identify a visitor's computer uniquely on the internet.

Stateless Tracking: Does not store any identifiable information on a user's computer. A combination of unique signatures about each computer is stored in the tracking server, which can identify a computer with a relative high accuracy, but not as precisely as stateful tracking methods.

Crime Identification Using Traffic Analysis of HTTP Botnet

Directorate of Technical Education, India

INTRODUCTION

A botnet is a network of malware infected systems that are controlled by an attacker through a Command and Control (C&C) channel. The attacker, also called the botmaster, controls the infected systems that are called bots or zombies. Various types of cyber-crimes are done by the botmaster with the help of these bots. A group of bots under the control of a botmaster is called a botnet. The general layout of a botnet system is shown in figure 1. The attackers use botnets to create disruption on the network or on a victim host either by utilizing the entire bandwidth in that network with bogus connections or by 100% CPU utilization on the victim host. This is through commanding the compromised bots to overload the resources of the victim machine/ network, to the point that it stops functioning resulting in denial of access. Such an attack is called a denial of service (DoS). Botnets can be used by botmaster to perform distributed denial-of-service (DDoS) attack, steal data, send spam, and access the device and its connection. These cyber-crimes are constantly evolving and hence the list of cyber threats can at no stage be considered exhaustive. Thus botnets are a great threat on the Internet by serving as the basic infrastructure for various distributed attacks.

Botmasters can use HTTP protocol for the C&C channel as majority of the Internet traffic uses HTTP and hence are allowed in most of the networks. Effectively, bots hide their communication within the normal HTTP traffic as it is not easy to block this service as a precautionary measure. This fact makes the HTTP-based C&C communication stealthier. Centralised C&C channels are prone to single point of failure as the C&C channel if detected and stopped, results in the loss of the communication channel between the compromised hosts. The advantage of centralised C&C channels is that they are simple and easy to setup as highlighted in Gu and Perdisci (2008). Botmasters have moved to peer-to-peer (P2P) C&C architecture to make their bots more powerful and stealthy.

Bots run automated programs that are designed to execute specific scheduled activities or to respond to commands in a particular manner. Hence, it is expected that the botnet generated traffic should always be having an apparent structure and regularity in the behavioral pattern. This is because the normal user behaviour is totally unpredictable, random and complex. This is attributed to the innumerable online applications and resources available for users. Hence the normal traffic differs from the botnet communication traffic, which is systematic and consistent in behaviour.

Several detection strategies have been developed in the available literature for botnet detection like up-to-date anti-virus software, signature-based intrusion detection systems for IRC/botnet traffic and traffic flow monitoring for known C&Cs. These detection techniques differ based on the C&C mechanism being centralised architecture (IRC, HTTP) or peer to peer (P2P) architecture or hybrid P2P/Centralised architecture. Detection also varies depending on other factors such as area of deployment, data captured for the detection system, etc.

Figure 1. Typical botnet system

This work proposes a technique to collect and analyse HTTP botnets. The deficiency of publicly available botnet datasets creates the characterization of botnet traffic difficult. Hence, HTTP botnet analysis plays a key role in the design of an effective detection system due to the fact that the foremost task in the process of mitigation of a threat is its characterisation. The network traffic generated by the HTTP botnets is analysed based on various features which could be used to develop an effective detection model. In this work a framework was developed in order to build HTTP botnets in a controlled environment. Analysis of the botnet traffic shows that periodicity is a main feature of HTTP botnets. This is because of the HTTP bots periodically contact the botmaster for commands and control messages by connecting to particular URLs or web pages. In addition the bots also report their status and attack results to the botmaster. This can be utilised to build behavioural detection models at network layer as reported in the work of AsSadhan et al. (2009). Signatures of the bots that were set up are also obtained, which can be used in signature-based detection. Further analysis was done using machine learning based classification as well as periodicity analysis. The results demonstrate the superior detection performance with 100% accuracy and detection of the proposed method using the hybrid periodicity analysis.

The rest of this paper is organized as follows: The state-of-the-art of botnet structures and its detection approaches are discussed in the next section. The system architecture is subsequently discussed followed by solutions and recommendations. The paper concludes after identifying the future directions of research.

BACKGROUND

A botnet is usually established by a botnet writer developing a program, called a bot or agent, and installing the program on compromised computers on the Internet using various techniques as demonstrated by Yu et al. (2015). As botnet has now become one of the major threats in the present attack landscape, many researchers are rigorously exploring the detection, mitigation and prevention of botnets. Available literature provides details of previous research work that are carried out aimed at distinguishing or detecting HTTP-based bots, many of which use network communication features as identifiers of botnet behaviour. In the work of Khattaket al.(2014), the authors have given a detailed review of botnet behaviour, detection and defence. Several studies and researches have been carried out in order to collect and analyse the malware activities like in the work of Baecher et al.(2006), Cooke et al.(2005), and Freiling (2005). A detailed study of botnet activities by a multifaceted approach to collect malware is carried out in the work of Rajab et al. (2006). Detection systems have been developed for different

C&C channels such as IRC, as seen in the work of Awadi (2015), HTTP, and P2P. Binsalleeh et al. (2010) present a technical analysis of Zeus crimeware toolkit, which is one of the powerful crimeware tools that emerged in the Internet underground community. Zeus has reportedly infected a large number of computers around the globe. The analysis uncovers the various obfuscation levels and sheds light on the resulting code. Grizzard (2007) provides an overview on the peer-to-peer based architecture of botnets that are most resilient to detection as well as legal shutdowns. A case study of aKademlia based Trojan-Peacomm bot is also presented as an example. In the work of Krmicek et al. (2011), the authors propose DNS flow based techniques for Botnet Detection. Gu et al. (2008) present a general detection framework that is independent of botnet C&C protocol and structure, and requires no prior knowledge of botnets. They define botnet as a coordinated group of malware instances that are controlled via C&C communication channels.

Zhanget al. (2014) propose an approach that uses network based anomaly detection to identify botnet C&C channels in a local area network without any prior knowledge of signatures or C&C server addresses. Strayer et al. (2008) propose a botnet detection approach which examines flow characteristics such as bandwidth, packet timing, and burst duration for evidence of botnet command and control activity. Livadas et al. (2006) propose machine learning techniques to identify the C&C traffic of IRC-based botnet compromised hosts that are collectively commanded using Internet Relay Chat (IRC).

In the work of Perdesci et al. (2010), the authors classify malware according to similarities in URLs extracted from malware HTTP requests. Considering the large number of URLs in the malware traffic, the authors propose a strategy with two steps of clustering process that includes coarse-grained and fine-grained clustering. The authors extract all malware HTTP requests, including both command requests and other benign operations such as connectivity checks. Therefore, their approach in the work is vulnerable to noise injection and malware obfuscation techniques. Another technique is presented in the work of Wurzinger et al. (2009). They extract statefull signatures by observing malware traffic during longer observation periods. It applies the change point detection algorithm on malware traffic in order to detect responses attributable to a command issued by the botmaster. It further analyzes the traffic snippet that just precedes the changing point in order to extract signatures of bot commands. As in the work of Perdesci et al. (2010), the method proposed by Wurzinger et al. (2009) is also vulnerable to noise injection, where a malware hides its change points within the noise traffic so that they are unidentified. There are lot of available literature albeit distantly from our work and those include the work of Li et al. (2006), Yegneswaran et al. (2005), and Newsome et al. (2005), where the network signatures are extracted.

The main challenges with HTTP Botnet detection are the following; first, the botnet communication protocol is very similar to the normal traffic flows, which makes it difficult to identify the botnet communication. These botnets usually get commands by constructing legitimate HTTP requests through the HTTP protocol making it completely stealthy. Second, due to the skewness of botnets in a large network, the volume of malicious traffic generated by botnets is very small. This is because of the rarity of the services offered by botnets like the download of commands whereas the valid and benign HTTP servers contain a variety of services to offer. Hence, there are a large number of HTTP requests from those valid and beneficial services. The HTTP requests from botnets will be too less in number. This limits the identification of bot communication embedded within the large volume of normal traffic. There will be millions of GET requests in which a few tens will be due to HTTP Botnets. It is hence necessary to filter out the benign HTTP flows to analyse the HTTP Botnet traffic flows.

Figure 2. Experimental setup

FOCUS OF THE ARTICLE

System Architecture

Malware analysis plays a significant role in the design of an efficient botnet detection system. Various leaked versions of the bot binaries/builders are taken from Internet and are analyzed on a sandboxed environment and the generated network traffic is captured. The botnet executable files are either directly available or a botnet builder program can be used to build the executable with the required configuration. A typical bot configuration includes C&C server address, update interval, drop name, etc. The bot control panels are hosted using PHP files available with the bot, after editing the database host, username and passwords. The network traffic generated by the bots help to identify the communication pattern and protocol used by the botnet, which may be directly used for implementing a signature based detection system. The system for recording and analysing the HTTP botnet traffic is discussed in this section. Traffic instances are analysed to know the characteristics of botnet communication. Traffic pattern of attack instances are analysed for a specific duration of time. The experimental setup for data capture is shown in figure 2.

The experimental framework consists of two parts; a local area network and a remote server. The star topology local area network is connected through a border router to the Internet. The switch used in the LAN is an eight port switch. The LAN connects to the Internet through a gateway router as shown in the figure 3. The router consists of two interfaces. IP Masquerading is done along with firewall to set up the router as shown in figure 3. It includes a system for packet capture and for storage. In addition to these hardware components, the framework has components for data capture and analysis.

SOLUTIONS AND RECOMMENDATIONS

System Implementation

The system implemented for the botnet data analysis is explained in this section. The system should essentially include a C&C channel for communication between the bots and the C&C server through a router as shown in figure 2. This setup is achieved by a web server implementation of C&C server and a LAN connecting the bots. The bots are the hosts on the LAN. The remote C&C server is accessed by the bots in the LAN through a router that connects it to the Internet. Each of the components involved are explained in the following subsections.

Figure 3. Diagram showing the block components of router that connects the internet to intranet

C&C Server

The proposed system sets up malwares in a controlled environment. The implementation of malwares is carried out on virtual machines as a security precaution. The C&C channel is of centralised architecture as the botnets setup are HTTP botnets. C&C server is a web server hosted on a Windows 7 machine that is connected to Internet using 4G data card. The web server (C&C Server) is set up using Apache web server along with MySQL. These C&C panels are setup using an open source solution stack package XAMPP. XAMPP is a third party customized software that is completely free, easy to install and manage Apache distribution containing MySQL, PHP, and Perl. Port 80 was kept open for the server to listen to the incoming connections. However, XAMPP comes with its own set of insecurities if not configured properly. A number of C&C panels have been compromised after mapping the XAMPP deployment and exploiting inherent security issues. XAMPP is configured in an open manner to allow developers all flexibility to do anything they want to experiment with.

The missing security features in XAMPP are listed here:

- MySQL administrator has no password.
- MySQL daemon is accessible via network.
- Examples are accessible via network.
- PhpMyAdmin is accessible via network.
- ProFTPD uses the password “lampp” for user “daemon”.

Hence, even a small mis-configuration in deployment of XAMPP could result in serious impacts. In this work XAMPP was configured to listen on machine’s public IP, which was registered with No-IP so that dynamic IP act as static IP by the dynamic DNS service provided by them. The Control Panel and databases for each bot were set up on the server.

Router

The router is set up using Linux Mint machine. Linux Mint is a community-driven Linux distribution based on Debian and Ubuntu that strives to be a “modern, elegant and comfortable operating system, which is both powerful and easy to use”. Two interfaces are needed to configure Linux Mint machine as a router. The two interfaces are classified as internal interface and external interface. Internal interface, i.e. the interface which connects to switch (LAN) is an Ethernet card or LAN card. The external interface

was a 4G data card. The internal interface is referred as eth0 and the external interface is referred to as ppp0 as referred by the Linux machine. Setting up of the router includes the following steps:

1. The decision of the IP range of the LAN and the configuration of internal and external interfaces. The internal interface eth0 is manually set up and the external interface ppp0 is configured automatically as it has DHCP installed in it.
2. IP masquerading is enabled to allow machines with private, non-routable IP addresses on the network to access the Internet through the machine doing the masquerading. Traffic from this network destined for the Internet must be manipulated for replies to be routable back to the machine that made the request. To do this, the kernel must modify the source IP address of each packet so that replies will be routed back to it, rather than to the private IP address that made the request, which is impossible over the Internet. Linux uses Connection Tracking (conn-track) to keep track of which connections belong to which machines and reroute each return packet accordingly. Traffic leaving the private network is thus “masqueraded” as having originated from the Linux Mint gateway machine. This process is referred to in Microsoft documentation as Internet Connection Sharing. IP Masquerading can be achieved by editing the custom ufw rules in the Linux machine

Hosts

Host computers are set up as virtual machines with Windows operating system. These virtual machines run on a Linux platform. The host computers are connected to the network of Linux machines in a bridged mode so that these machines act as a normal system in the network with the same IP range. Hence, these machines could be connected to the switch as in a normal LAN. The virtual machines are chosen to use them as the bot infected machines. The use of virtual machines makes it easy and secure. The LAN interfaces of the hosts need to be configured manually as DHCP server is not installed in the router.

Data Capture

Data capture is done using Wireshark packet sniffer. Wireshark is set to listen to the interface connecting the LAN so that the traffic between the hosts and C&C could be captured. Netflow data is also captured using a software implementation of Netflow probe and a collector program.

Results and Analysis

HTTP botnets named Zeus, Aldi and Umbraloaders are set up and analysed with the framework already discussed.

The Zeus bot client side software is an infection that happens via a drive-by-download, one of the possibly stealthiest forms of infection, or via other means from social media and phishing sites, tempting the user to run an arbitrary executable. Infection can also occur simply through getting access to a computer and using any media for running the bot software. Once infection is successful, the client runs silently on the victim machine, hiding itself to avoid detection. There is no visual sign of this activity to the user. The bot Zeus will delete all the cookies in Internet Explorer and this is to force the user to re-login to the services managed by the user, and also lets Zeus grab the credentials and secret information. The client is configured with a specific time that tells it how often it should run and keep-alive check-ins, update the Command and Control server with new collected information, as well as dynamic configuration updates.

Figure 4. Periodogram of aggregated traffic flow

Aldi Bot is an inexpensive DDoS bot that is growing in popularity. Aldi Bot provides an attacker a simple support mechanism within an organization, which can lead to a much larger security breach. Usually severe attacks involving the exfiltration of sensitive data typically start with one smaller compromise that is then leveraged for additional access like getting a remote or a physical access to a machine by password cracking and then acquiring higher privileges using buffer overflow techniques. Additionally Aldi Bot steals passwords, and passwords are often re-used for convenience for long period of time. Without proper monitoring of system and network activity, such infected nodes can be long-lived and pose significant risk.

The control panel of the HTTP botnets Zeus, Aldi and Umbraloaders is available on the C&C server with various options for attack and stuffs like remove, logout etc. Each communication of Aldi bot contains an HTTP GET request to the C&C server which includes the name, local address, windows version and unique ID generated by the bot. The actual request URL is shown below:

```
/gate.php?hwid=< ID>&pc=<PC NAME>
&localip<IP>=&winver=<WINDOWS VERSION>
```

The botmaster replies with an HTTP OK reply along with text data, which contains commands if any that are issued by the botmaster. When stolen data is exported, a &steal= parameter will be used in the URL that will also include the hwid value as such:

```
gate.php?hwid=<ID>&steal= <URL|USERNAME
|PASSWORD>.
```

The captured data indicates that the bot uses a custom user agent in HTTP requests, “Aldi Bot FTW! :D” and this unknown string can be used for signature based botnet detection.

Umbra Loader C&C panel provides the options for downloading and executing malware, updating bot and uninstalling bot. Each communication session consists of two HTTP POST commands through which the bot connects to the sever using its unique ID and version information. The server does not recognise the internal IP of the infected host in the process. The commands issued by the botmaster are encoded as plain text and appended with the HTTP OK reply for the second POST command. Detailed analysis reveals that the bot uses a custom user agent umbrain the HTTP header and text based data contains a unique ID generated by the bot and a mode number. These features may be used to develop a traffic signature of the bot.

Network traffic analysis is heavily used to detect anomalous and malicious traffic originating from the infected end-user system to C&C panel and vice versa. The analysis shows that HTTP is being used by most of the botnets due to the advantage that most of the traffic in today's web consists of HTTP traffic and it cannot be totally blocked or filtered. A common trend observed among all the analysed bots was that they tend to have a periodic communication with the botmaster and commands are gathered during this phase. The HTTP traffic can be either periodic or non-periodic. That clearly states that periodicity alone is not sufficient for HTTP based botnet detection. However, the periodical pattern communication need to be used as a complementary factor along with other HTTP Botnet detection techniques. Even though periodicity cannot be claimed to be an exclusive feature of bots, they are much common among bots. In order to check periodicity, the periodogram of the traffic flow start time sequence of the aggregated traffic and the normal traffic are plotted. Aggregated traffic included normal and attack traffic. This is shown in the figure4 and figure5 respectively. Comparison between the two periodograms shows that the aggregated traffic exhibits periodicity and hence it can be inferred that the botnet traffic is periodic. Bots were using encrypted communication, which were observed from the traffic traces. This makes it nearly impractical to decode and correlate, hence signature-based techniques would not be sufficient for detection of these bots. Therefore it is better to design a behavioural detection model to detect these bots.

The test data was collected by running the system as pcap files and these files contained the botnet traffic. Using softflowd, Netflow was exported to the local host on a high valued port and collected using the collector program. The periodicity detection algorithm was subsequently applied to the netflow data. The periodicity detection successfully identified the botnet traffic.

Machine learning using random forest was used to model the botnet traffic for an effective detection. There was 100% detection with zero false alerts as shown in table 1. The evaluation metrics are: Precision=1, Recall=1, F-score=1, and Accuracy=100%

FUTURE RESEARCH DIRECTIONS

The HTTP Botnets due to the inherent stealthy behavior, are extremely difficult to be detected. The method of botnet detection using periodicity does not provide a comprehensive solution against HTTP based botnets as periodicity is just one of the characterizing feature of botnets. However, our experimental results show that this approach considerably increases the botnet detection rate on a network. The research to mitigate and prevent botnets is still on a long run, but our solution approach adds a new level of defense.

A common trend observed among all the analyzed bots is that they tend to have a periodic communication with the botmaster and commands are gathered during this phase. This can be used to design behavioural botnet detection model based on periodicity and machine learning techniques. In this work the training of the machine learning algorithm was undertaken on a limited number of samples and as a

Figure 5. Periodogram of the normal traffic flow

Table 1. Periodicity detection and random forest detection for the botnets

Traffic pattern	Count of bots	Periodicity and Random Forest
Normal	0	NA
Botnet	4	165.254.92.221 to 165.254.145.198 165.254.214.185 to 165.254.145.198 165.254.251.103 to 165.254.145.198 165.254.78.166 to 165.254.145.198

future research more samples need to be collected for building a better model that can detect the novel botnets. It is necessary to include some features other than the periodicity that enable the defenders to better detect the botnets as periodicity does not provide a comprehensive solution against HTTP based botnets.

CONCLUSION

To detect and protect from the attacks caused by botnets, it is important to harness the power of a thorough analysis including periodicity analysis. There are several detection schemes proposed for detecting botnets. This paper proposed an analysis of HTTP botnets by setting the botnets in a controlled environment. Based on the analysis, signature of the bots that were setup is found out. This was used in signature based detection of these bots. In order to detect the new botnets, machine learning classifier using random forest was made use of. The detection of botnets at local networks is possible with this simple work where the botnet infected client machines are detected and hence eliminated from the net-

work. The results demonstrated the higher detection of botnets using periodicity analysis and machine learning techniques.

KEY TERMS AND DEFINITIONS

Botmaster: Botmaster is the master of bots on the network. A botmaster is responsible for keeping the bot online, sending control commands to bots for its operation, making sure to fix issues with bots, and set a set of rules for bots to function.

Botnet: A botnet is a collection of bots. Botnets originate many types of attacks like distributed denial-of-service attack (DDoS attack), data theft, spamming, and intrusion to systems and networks.

Bots: Any system connected to Internet becomes a bot when it runs automated tasks or scripts over the internet. Majority of the malicious web traffic gets originated from bots.

C&C Server: A command and control server (C&C server) is a system that issues directives to other connected systems that have been infected with rootkits or other types of malware such as ransomware.

Firewall: A firewall is a network security system that allows or denies incoming and outgoing network traffic based on predetermined security rules.

HTTP: HTTP means HyperText Transfer Protocol. HTTP is the underlying protocol used by the world wide web and this protocol defines how messages are formatted and transmitted, and what actions web servers and browsers should take in response to various commands.

Intrusion Detection Systems: An intrusion detection system (IDS) is a hardware device or software application that monitors a network or systems for malicious activity or policy violations.

IRC: Internet relay chat (IRC) is a system for chatting that involves a set of rules and conventions and client/server software.

Periodicity: Periodicity is the occurrence of similarity in more or less regular intervals and is a property exhibited by many processes that are of interest in a variety of scientific disciplines.

Random Forest Classifier: Random forest classifier uses a set of decision trees from randomly selected subset of the training data and then aggregates the decision from each set to arrive at the final decision class of the test data. This improves accuracy and avoids over-fitting and hence better than decision tree algorithms.

Router: Router is an inter-networking device that forwards the packets from one computer network to another. Routers perform the traffic route finding on the Internet by means of a routing table.

Signature-Based Classifier: Signature-based classifier classifies items based on an entry in a lookup table with signatures and the corresponding class labels. Hence, this classifier is not efficient in detecting novel patterns/signatures.

Hybrid Artificially Intelligent Multi-Layer Blockchain and Bitcoin Cryptology (AI-MLBBC): Anti-Crime-Theft Smart Wall Defense

Murad Al Shibli

Abu Dhabi Polytechnic, UAE

INTRODUCTION

This chapter presents an integrated secured framework of blockchain and bitcoin cryptology with the artificial intelligence of neural networks and machine learning. Recently blockchain has been received special attention and used as a new platform for digital information and to store encrypted data and process secure digital transactions. Noticeably, the majority of blockchain cryptocurrency technology is structured based on the elliptic curves digital signature algorithm (ECDSA). In particular, Bitcoin uses special elliptic curves digital signature algorithm (ECDSA) called secp256k1. Losses of personal and organizational data have been reported and occurred due to security breaches of data at minor and major scales using traditional transactional and financial platforms. Furthermore, data on blockchain and Bitcoin platforms are assumed to be highly encrypted and secured state. This feature enable blockchain to be an ideal system to save confidential and personal data as well as sensitive organizational and financial information. Although blockchain and bitcoin databases are encrypted using private keys, but there are many cryptocurrency bitcoin wallets have been reported hacked which resulted in losing millions of dollars. Breaching blockchain can lead to exposing sensitive data to high risk. The artificial intelligent neural networks (AINN) algorithms possess the capability features of processing and operating encrypted data and will lead to minimal risk. Pretrained convolutional neural network (CNN) training is proposed to be implemented a part of the block chain to protect personal data and information as third wall defense against hacking. CCN is used to extract learned image features and use those features to train an image classifier with single pass making advantage of machine learning tools features.

In this chapter presents a literature survey is presented, mathematical background of elliptic curves for real and finite prime fields is introduced, elliptic curves cryptosystem is addressed, and bitcoin digital signatures are demonstrated. Moreover, a novel integrated cryptology approach of artificial intelligence based blockchain and bitcoins by introducing a multilayer security layer and neural networks machine learning and big data mining. Specifically, this revolutionary safe combination criteria is structured by implementing a coupled private key elliptic curves digital signature in order to securely enter into the blockchain and process encrypted data using neural networks. Furtherly, encrypted big data can be processed by neural networks linear regression and out-of-memory tall arrays criteria. Moreover, artificial intelligent machine learning of photography can be encrypted-decrypted by using a pertained Convolutional Neural Networks (CNN) and by utilizing Singular Value Decomposition (SVD) and XOR-Secret cipher key.

DOI: 10.4018/978-1-5225-9715-5.ch075

In this chapter, Section 1 will introduce a literature survey, Elliptic Curves Defined Over Real Field is presented in Section 2, Elliptic Curves Cryptosystem Over Finite Prime Fields is introduced in Section 3, Elliptic Curve Cryptographic Algorithm is addressed in section 4, moreover, Bitcoin Elliptic Digital Signature Cryptosystem is presented in Section 5, Multilayer Elliptic Curve Digital Signatures are introduced in Section 6. Moreover, Protection of Data Using Pretrained Convolutional Neural Network (CNN) and Singular Value Decomposition (SVD) is proposed in Section 7 along with simulations results. Finally, conclusions are drawn in Section 8.

BACKGROUND

In 2008, Bitcoin was introduced for the first time by Satoshi (2008) as a new type of crypto-currency. Bitcoin as a peer-to-peer digital transaction is structured based on non-centralized chain that is not governed by any central financial bank or any government. Nakamoto proposed to use cryptographic transactions to allow any two parties to transact directly with each other without going through the traditional practice of a trusted third party. Due to this new concept and it has been public used worldwide. The mathematical algorithm and transactions of Bitcoins are built based on elliptic curves. An overview of Digital Signature Algorithm (DSA) and its Elliptic Curve Digital Signature Analogue (ECDSA) and related application in the blockchain and Bitcoin technologies are presented in article of Kikwai (2017). To ensure high security levels for users recommended Elliptic Curve Domain Parameters (ECDP) are introduced in the research work reported by Brown doe SEC1 in (2009) and for SEC2 in (2009). The Wireless Application Forum (2001) has developed the wireless transport layer security and associated wireless application protocol WAP-261-WTLS-20010406-a in order to provide privacy, data integrity and secure authentication between two communicating applications. The American National Standards Institute (2001) and (2005) has identified methods to generate and verify digital signature to secure messages and data using ECDSA in two published standards. These curves and parameters are derived based on Elliptic Curve Cryptography regulated by Standards for Efficient Cryptography Group, ANSI and IEEE.

Multiple elliptic curves digital signature algorithm is proposed in research of Bi, Jia & Zheng, (2018). This algorithm will allow selecting many elliptic curves and editing elliptic curve parameters. This scheme is shown to be secure and efficient with two elliptic curves as recommended. Important questions about Bitcoin are addressed in the book published by (Narayanan, Bonneau, Felten, Miller & Goldfeder, 2016). It addresses the principles of Bitcoin, what makes it different, how bitcoins are anonymous, associated applications, regulations, and future trends. An overview of a bitcoin digital transactions is presented in the thesis work of Crossen, S. (2015). Individual transaction details and security, associated blocks as well as Bitcoin public ledger are highlighted along with mathematical Elliptic Curve background. Elliptic Curve Cryptography using the secp256k1 curve, Elliptic Curve Digital Signature Algorithm, and Secure Hash Algorithm 256 (SHA256) are also discussed. Research work reported by (Haddaji, Ouni, Bouaziz & Mtibaa, 2016) addresses the benefits of the implementations of the electronic signature ECDSA compared to the digital signature algorithm (DSA) used to authenticate compressed videos of H.264. The added value of this algorithm is tested on a set of videos to compare strength, add-time, speed, number of gates of some hashed videos using MD5 functions. The research work Ghosh & Nath, (Nov. 2014) presents a theoretical study of data encryption using artificial neural networks (ANN) using Neural Cryptography. Using feedback, ANN is used to produce efficient data encryption systems.

ANN composed of one or multilayer perceptron models are reported to be more efficient in encrypting systems based on feedback in the field of cryptography.

Bitcoin systematic analysis of broken primitives are presented by (Giechaskiel, Cremers & Rasmussen, Feb. 2016) in which Cryptographic blocks and related effect on the Bitcoin security are identified. Primitive breakage range of simple privacy violations and full breakdown of the bitcoin currency analysis is revealed. Many findings and recommendations for Bitcoin threat of broken cryptographic primitives are introduced. Unique mistakes and vulnerabilities associated to the implementations elliptic curve cryptography (ECC), are reviewed and revealed unique published by Bos, Halderman, Heninger, Moore, Naehrig, & Wustrow (March 2014). Bitcoin and other protocols such as secure shell (SSH) and transport layer security (TLS), and Austrian e-ID are studied. It is found that only 10% of the systems support ECC and vulnerabilities are highly exposed.

The concept of Elliptic Curve Digital Signature Algorithm (ECDSA), its mathematical context and successful practice methods are introduced by Linke (May 2014). ECDSA is considered as asymmetric authentication systems which is based on a private key at authenticator level and another public key used at host level to validate the authentication. On the other hand, the symmetric authentication scheme systems used a common secret keys shared by both the user and host. Accelerated verification scheme of Elliptic Curve Digital Signature Algorithm (ECDSA) in wireless sensor networks (WSN) is proposed by Kheradmand (2013). The delay is due to the fact that ECDSA requires an extra point and two multi scalars to verify WSN signature. If cooperation among sensor nodes is exploited then the delay can be solved. A new efficient and optimal scheme is proposed to provide a threshold DSA/ECDSA algorithm proposed by (Gennaro1, Goldfeder & Narayanan, 2016). This algorithm will enhance the security of Bitcoin wallets to avoid any thefts. Implementation of elliptic curve P-192 with ANSI X9.62 ECDSA and associated security is described in the work of (Khalique, Singh & Sood, 2010). The adoption of ECDSA as a standard at ISO, ANSI, IEEE and NIST is reported in 1998, 1999, 2000, and 2000, respectively.

Elliptic Curve Cryptography backgrounded with text and imaged background implementation is briefed in the paper of (Kolhekar & Jadhav, July 2011). This is due to the robustness and security of the mathematical compared to other schemes. Prediction of future facts of the Ethereum blockchain can be explored by Deep Learning (DL) methods is reported by (Besarabov & Kolev, 2018). This prediction approach is implemented by using as the transaction count and the account balance distributions. DL is performed to create reusable blockchain framework to provide data, processing and storage. New US patents on blockchain-enabled peer-to-peer drone delivery service, cloud, satellite networking services and cryptocurrency are reported by Al-Shibli (2019).

ELLIPTIC CURVES DEFINED OVER REAL FIELD

Elliptic curves are defined by cubic equations and are totally different from ellipses or ellipsoids. In a two dimensional plane, the elliptic curve E is a cubic curve described over a real domain $\mathbf{R}$ whose points satisfy the following Weierstarss equation

$$E: y^2 + axy + by = x^3 + cx + d \quad (1)$$

where x and y take on values in the real number field, and the coefficients a , b , c , d are all have real number values. For the purpose of applicability, it is very common reduce the Elliptic curves introduced in Equation (1) to have the following reduced form

Figure 1. Elliptic curve plot over $\mathbf{R}$ for: $y^2=x^3-x+3$ ($a = -1$, $b = 3$)

$$E: y^2 = x^3 + ax + b \quad (2)$$

Because the highest order (exponent) is 3, the elliptic curves are said to be cubic equations. Moreover, a zero point is defined with an elliptic curve as a single element denoted O (also called the point at infinity). In order to plot the elliptic associated curve, Equation (2) can be put in the square root form as:

$$y = \sqrt{x^3 + ax + b} \quad (3)$$

For every value of x in Equation (3), negative values of y plot are obtained if specific values of a and b are used. For every quadratic residue x of the elliptic curve defined in (3), there are two solutions exist: y and $-y$ exist. Examining elliptic curves is found that the associated plots are symmetric about x -axis ($y=0$). Because of this symmetric property, for every point $P=(x,y)$, there is a negative or inverse negative point $-P=(x,-y)$ such that $P+(-P)=O$. The identity point O can now be added to the elliptic curves group definition such that the group elements can be defined for all points (x,y) on some elliptic curve $=x^3+ax+b$, and the identity point O . This leads to what is called as an infinite group.

Furthermore, the identity point O and all points on located on an elliptic curve form cyclic subgroups.

It is reported that arithmetic operations of elliptic curves over real domains $\mathbf{R}$ usually leads to irrational numbers and computer truncation errors that and improper memory storage. Therefore, it is recommended to work over finite prime fields associated with elliptic curves. A finite prime field of order q such that $q=p^k$ in which p is a prime and p and k are integers that satisfy the modified original Equation (2) given a domain parameters over $\mathbf{F}_q: T=(q,a,b,G,n,h)$

$$y^2 = x^3 + ax + b \pmod{p} \quad (4)$$

Equation (4) of an integer p identifying the finite prime field $\mathbf{F}_q$, given that $4a^3+27b \not\equiv 0 \pmod{p}$, where p is a large prime. The two coefficients $a, b \in \mathbf{F}_q$, specifying an elliptic curve $E(\mathbf{F}_q)$ defined in Equation (4) with randomly selected elements on $E(\mathbf{F}_q)$ called a base point $G=(x_G, y_G)$. The base point G has an order n which is a large prime that yields $nG=O$ which is defined earlier as the zero element of the field such that $n > 4\sqrt{p}$ and $n > 2^{160}$. The cofactor h is an integer that satisfies $h \neq E(\mathbf{F}_q)/n$. Moreover, the non-singularity condition $4a^3+27b$ meant not to be congruent to 0 modulo p .

Figure 2. Point addition over the elliptic curve: $y^2 = x^3 - 3x + 4$ ($a = -3$, $b = 4$)

The elliptic equation described in (2) should satisfy the condition $p \neq 2$. In case that $p = 2$, then Equation (4) will yield to the form:

$$y^2 + xy = x^3 + ax + b \quad (5)$$

Over $\mathbb{R}$, there is a natural geometric construction that transforms the points of an elliptic curve into an abelian group having O as the neutral element. In this addition of points will be expressed for two points as follows. The addition for a group operation on $E(\mathbb{F}_q)$ of two points: $P_1 = (x_1, y_1)$ and $P_2 = (x_2, y_2)$, an additive third point $P_3 = (x_3, y_3) = P_1 + P_2$

$$x^3 = s^2 - x_1 - x_2 \dots \dots \text{mod } p \quad (6)$$

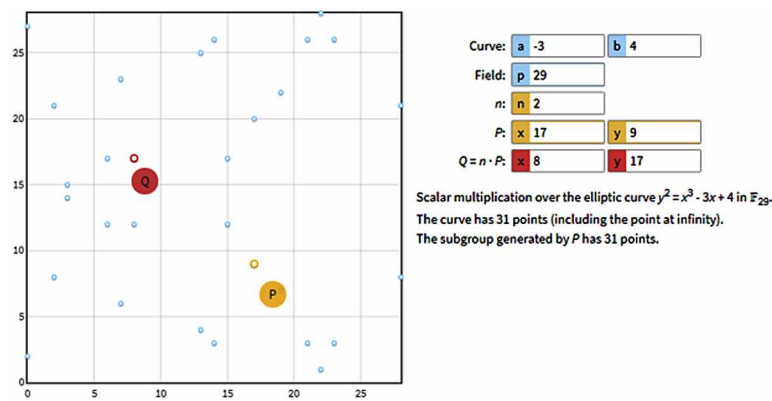

$$y_3 = s(x_1 - x_3) - y_1 \dots \dots \text{mod } p \quad (7)$$

$$s = \begin{cases} \frac{y_2 - y_1}{x_2 - x_1} \text{mod } p, P_1 \neq P_2 \\ \frac{3x_1^2 + a}{2y_1} \text{mod } p, P_1 = P_2 \end{cases} \quad (8)$$

It is interested to know the total number of points (N) of an elliptic curve given modulo p . It is found that N is almost nearby the prime p as follows:

$$p + 1 - 2\sqrt{p} \leq N \leq p + 1 + 2\sqrt{p} \quad (9)$$

adding two points $P + Q = R = (-2.0, 1.4) + (0.9, 1.4) = (1.1, -1.4)$ doubling a point $A + A = 2 * (0.9, 1.42) = (-1.76, -1.96)$

Figure 3. Scalar multiplication over the elliptic curve in real field R for $y^2 = x^3 - 3x + 4$ Figure 4: Doubling a Point of an Elliptic Curve in Finite Prime Field F : $y^2 = x^3 - 3x + 4$ 

ELLIPTIC CURVES CRYPTOSYSTEM OVER FINITE PRIME FIELDS

The entire group of an elliptic curve $E(\mathbb{F}_q)$ is not practically needed as a whole, instead a cyclic subgroup is sufficient. A sufficient large cyclic subgroup of $E(\mathbb{F}_q)$ can be generated by selecting the parameters: a, b, p, k and base point $G \in E(\mathbb{F}_q)$. These parameters are shared publicly in Elliptic Curves cryptosystem and used to produce public keys. In general it is assumed that any point P on the elliptic curve can be generated and expressed in terms of the base point G and a non-negative integer n as follows:

$$P = G + G + \dots + G = nG \quad (10)$$

Based on the Equation (10), it is easy to calculate the new point P provided a base point G and an integer n . But on the other hand, it is very hard and infeasible to do the opposite and find the integer n given the point $P = nG$. Furthermore, double and add scheme is defined for an elliptic curve group element P and n is an integer, then $n \cdot P$ is a multiple copies of the base point P added together using point addition. Figures 4 and 6 demonstrates some examples of doubling and multiples of Elliptic Curve in Finite Prime Field. Doubling a point $P + P = Q = 2 * (17, 9) = (8, 17)$

Figure 5. Multiples of the base point $P(0, 2.0)$ over the Prime Field: $y^2 = x^3 - 3x + 4$ with Modulus 29

ELLIPTIC CURVE CRYPTOGRAPHIC ALGORITHM

In order to perform a successful and secure elliptic curve cryptographic algorithm, the following parameters are required:

1. A finite elliptic cubic curve coefficients a and b ;
2. A finite prime modulus p ;
3. A base point $G=(x,y)$ with which point multiplication will be performed such that $n \cdot P = O$. The order of G is identified by the value n . It should be noted that n must be a large prime number. The size of n determines the level of the security.

Hash Function: Hash function H is very important to create and verify a digital signature. It is defined as an effective computational function that needed to map a random length binary string to a fixed length binary string. Hash function H should meet the following technical specifications:

1. **Collision Resistance:** An infeasible computational condition to find two distinct inputs r_1 and r_2 such that $H(r_1) = H(r_2)$;
2. **First Pre-Image Resistance:** For any given output z it is not feasible to find an input such that $H(r) = z$.
3. **Second Pre-Image Resistance:** An infeasible computational condition for a given input message r to another inputs r' such that $H(r) = H(r')$;

This is crucially important for digital signatures as primitive cryptographic that is based on authentications, authorization and non-rejection.

Figure 6. Bitcoin elliptic curve plot over $R: y^2=x^3+7$ ($a = 0, b = 7$)

Figure 7. Bitcoin point addition over the finite prime field for $y^2=x^3+7 \bmod 97$

BITCOIN ELLIPTIC DIGITAL SIGNATURE CRYPTOSYSTEM

The Bitcoin invented by Satohsi Nakamoto is defined over a finite prime field of order q such that $q=p^k$ in which p is a prime and p and k are integers that satisfy the Equation (2) given a domain parameters over $\mathbb{F}_q: T(p,a,b,G,n,h)$

$$y^2 = x^3 + 7 \pmod{p} \quad (11)$$

Figure 6 demonstrates the plot of the Bitcoin Elliptic Curve over $\mathbb{R}$: $y^2 = x^3 + 7$ ($a = 0, b = 7$). On the other hand, plotting Bitcoin Finite Prime Field to display addition of points with a given modulus is shown in Figure 7. adding points $P(13,19) + Q(85,5) = R(78,61)$

Bitcoin Digital Algorithm

Define an elliptic curves digital signature algorithm (ECDSA) such that: $y^2 = x^3 + 7 \pmod{p}$.

A signer selects a random number $m \in [1, n]$ as a private key and calculate a public key $q = mG$

Phase 1: ECDSA Signature Generation: An initiator sends a message M as follows:

- Step 1: Compute a secure hash H such that $e = H(M)$;
- Step 2: Choose a random cryptographic integer k from the range $[1, n - 1]$ and then calculate $kP = (x, y)$;
- Step 3: Calculate r such that $r = x \pmod{n}$ and not to be zero. If zero, then go back to step 2.
- Step 4: Compute $s = k^{-1}(e + mr) \pmod{n}$;

Output: The cryptographic signature is (r, s) .

Phase 2: ECDSA Signature Verification: A receiver can check if the message M is true as follows:

- Step 1: Check that r and s are integers in $[1, n - 1]$, if not then the signature is not valid.
- Step 2: Calculate the hash H such that $e = H(M)$ as in phase 1.
- Step 3: Determine w as $w = s^{-1} \pmod{n}$;
- Step 4: Compute $u = ew \pmod{n}$ and $v = rw \pmod{n}$;
- Step 5: Obtain $R = uP + vQ = (x, y)$;

Output: The signature is valid if only if $r = (x \pmod{n})$. Otherwise it is not valid.

The modulus, base point, public key and private keys are demonstrated in Figure 8 and 9 of bitcoin digital signature.

ECDSA Signature

MULTILAYER ELLIPTIC CURVE DIGITAL SIGNATURES

This section aims to generalize using multiple elliptic curve signature to ensure a double security [4]. A combination of two or more signature can be used. For the purpose of generality, the elliptic curve domain parameters over a finite field $\mathbf{F}_q$ is defined by:

$$T = (q, A, B, C, n, H) \quad (12)$$

such that q is an integer specifying the finite field $\mathbf{F}_q$, two parameters $A, B \in \mathbf{F}_q$, and C is a base point $C = (x_c, y_c)$ exists on $E(\mathbf{F}_q)$ with a prime n as the order of C and an integer cofactor H such that $H \neq E(\mathbf{F}_q)/n$. All specifying an elliptic curve $E(\mathbf{F}_q)$ defined by the equation:

$$y^2 = x^3 + Ax + B \pmod{p} \quad (13)$$

Figure 11. CNN-SVD flow chart

All elliptic curve domain parameters over $\mathbf{F}_q$ must have the form:

$$[\log_2 q] \in \{192, 224, 256, 384, 521\} \quad (14)$$

The following Tables 1-3 demonstrate a selection of some of these recommended parameters [4]:

PROTECTION OF DATA USING PRETRAINED CONVOLUTIONAL NEURAL NETWORK (CNN) AND SINGULAR VALUE DECOMPOSITION (SVD)

As proposed by is proposed by (Al-Shibli, Marques, & Spiridon, Nov. 2018), in this section Pretrained convolutional neural network (CNN) training to be implemented a part of the block chain to protect personal data and information as third wall defense against hacking. CCN is used to extract learned image features and use those features to train an image classifier with single pass making advantage of machine learning tools features as shown in Figure 11. Images can be automatically loaded from image library and labeled based on the image folder name even if images do not fit in memory. Partial training of the image data can be performed in order to test the rest image data. Pre-trained CNN can classify images into object categories.

The Pre-trained CNN architecture is composed of some convolutional layers and some fully connected layers where the first layer is dedicated as an image input layer with given size and color channels. The CNN builds a hierarchical structure of input images, meanwhile the deeper layers contain higher-level features made based on the lower-level features of previous layers. A part of the training is to extract the image labels from the training data and test data and then these features extracted from the training images are used as predictor variables and fit with a multiclass support vector machine learning (MSVML) as shown in Figure 11. Therefore, the test images can be classified and labeled. The fraction of labels that the network predicts correctly represents the accuracy.

Figure 12. Sample 1 of the pre-trained images of the CNN

Figure 13. Sample 2 of the pre-trained images of the CNN

Figure 16. Block diagram of the encryption

CNN-SVD Criteria

- Step 1:** Load the target images from the image library store.
- Step 2:** Divide the image data into 60% training data and 40% test data.
- Step 3:** Exhibit some of image samples.
- Step 4:** Load a pre-trained CNN network.
- Step 5:** Display the CNN architecture.
- Step 6:** Identify the size of the input images and create augmented image data-storage.
- Step 7:** Extract the class labels from the training data and test data.
- Step 8:** Classify fit image by using support vector machine learning (SVML).
- Step 9:** Classify the test images using SVML model.
- Step 10:** Display sample test images with their corresponding predicted labels.
- Step 11:** Calculate image classification accuracy.

For the purpose of demonstration of pre-trained CNN blockchain based information and image processing and classification, sample images are used to represent 6 different categories: fingerprints, ID cards, passports, bank cards, bank statements, and bitcoin transactions. These sample images are unzipped and loaded as an image data-store. Image Data store automatically labels the images based on folder names and stores the data as an Image data-store object. A total of 30 images Split the data into 70% for training and 30% for test data. In overall, there are now 21 training images and 9 validation images in this very small data set. Three runs of some of these sample images are demonstrated in Figures 12-13. Meanwhile, the CNN labeling identification are depicted in Figures 14-15 with 100% accuracy.

Figure 17. Display of SIN card image which is encrypted by using SVD

In cryptography, encryption is the process of transforming information using an algorithm to make it unreadable to anyone except those possessing the photography, usually referred to as a key. The result of the process is encrypted information. The reverse process is referred to as decryption as shown in Figure 16. Cryptography involves the use of advanced mathematical procedures during encryption and decryption processes. Cipher algorithms are becoming more complex daily. There two main algorithmic approaches to encryption, these are symmetric and asymmetric. Symmetric-key algorithms are a class of algorithms for cryptography that use the same cryptographic keys for both encryption of image matrix and decryption of cipher image matrix. The keys may be identical or there may be a simple transformation to go between the two keys.

The proposed encrypt image based on SVD can be applied the colored images into grayscale images Al-Shibli (Oct. 2015). The encryption technique includes the SVD transformation of the resulted grayscale image; converting decimal numbers to binary numbers of the SVD matrix; converting decimal numbers to binary numbers of random vector as the first cipher key; running logical Exclusive OR as a second cipher key; adding noise to the image by using Poisson distribution as a third cipher key; implementing another stage of decimal-to-binary and logical Exclusive OR; running binary-to-decimal conversions; and finally obtaining the encrypted SVD matrix. The following 17 steps outline the encryption criteria in details along with testing results in Figures 16-17:

- Step 1:** Read image from graphics file.
- Step 2:** Convert RGB image or colored map to grayscale.
- Step 3:** Convert image to double precision.
- Step 4:** Display image in Handle Graphics figure.
- Step 5:** Convert image into SVD.

Figure 18. Display of encrypted SVD images of sin card image shown in figure 17

Figure 19. Display of reconstructed SIN card image by decryption of SVD images

Step 6: Return a vector containing the singular values of SVD.

Step 7: Round towards nearest integer.

Step 8: Convert decimal numbers of the vector to binary numbers.

Step 9: Convert decimal numbers of a random vector to binary numbers.

Step 10: Run Logical EXCLUSIVE OR of Step 8 and Step 9 to obtain the logical symmetric difference of elements of both vectors. $XOR(S,T)$ is the logical symmetric difference of elements S and T . The result is logical 1 (TRUE) where either S or T , but not both, is nonzero. The result is logical 0 (FALSE) where S and T are both zero or nonzero. S and T must have the same dimensions (or one can be a scalar).

Step 11: Generate random arrays from a specified Poisson distribution (Adding noise to the image).
 $R = \text{Random}(\text{Poisson}, A)$: Returns an array of random numbers chosen from the one-parameter probability Poisson distribution with parameter values A .

Step 12: Convert decimal numbers of the vector to binary numbers.

Figure 20. Pretrained CNN encryption-decryption identification of the blockchain information

Step 13: Run Logical EXCLUSIVE OR of Step 10 and Step 12.

Step 14: Convert decimal numbers of the vector to binary numbers.

Step 15: Convert to diagonal matrix. $\text{DIAG}(V, K)$ when V is a vector with N components is a square matrix of order $N + \text{ABS}(K)$ with the elements of V on the K -th diagonal.

Step 16: Convert to SVD using the diagonal matrix obtained in Step 15.

Step 17: Convert to encrypted image

In order to verify that the proposed technique is effective, SVD encryption-decryption of a SIN card image set has been implemented as depicted in Figure 17. This image is encrypted in three images as shown in Figure 18. For the purpose of validation, the SVD image matrices are then decrypted to recover and reconstruct the original SIN image which is successfully achieved in Figure 19.

The decryption process is the inverse process of encryption; the algorithm implements a logical Exclusive OR, decimal to binary conversion and then SVD transformation. Detailed algorithm of the decryption process with 7 steps is as follows:

Step 1: Run Logical EXCLUSIVE OR of Step 13 and Step 12 in Section IV.

Step 2: Run Logical EXCLUSIVE OR of Step 10 and Step 9 in Section IV.

Step 3: Convert decimal numbers of the vector to binary numbers.

Step 4: Convert to diagonal matrix.

Step 5: Convert to SVD using the diagonal matrix obtained in Step 4 in this current section.

Step 6: Convert to decrypted image.

Step 7: Display decrypted image with predicted label.

Furthermore to the analysis, Figure 20 demonstrate that the CNN encryption-decryption technique is crucially efficient in processing the drone image set. Initially, (1) pretrained CNN image training and testing steps are performed as start; then (2) the 17 SVD encryption steps are followed to generate an unreadable images; finally, (3) the decryption algorithm introduced earlier is used to recover the original images as demonstrated in Figures 12-18. In all runs, the pretrained CNN network is loaded as an input

to train this set of images. AlexNet network is used as a tool in this analysis. This network is used to train and classify images. This network is composed of 5 convolutional layers and 3 fully connected layers such that the first layer is used as the image input layer. Deeper layers contain higher-level features, constructed using the lower-level features of earlier layers. In order to get the feature representations of the training and test images the fully connected layer are activated. Meanwhile, lower-level representation of the images, earlier layers are used. Based on the training and test data, labels then are successfully extracted.

CONCLUSION

In this chapter an overview of multilayer neural networks and associated application to blockchain and bitcoin technology is presented along with prospective and future applications. Recently blockchain has been received special attention due to its encrypted data and secure digital of peer-to-peer transactions. It is noticed that blockchain has a strong potential to be used as a digital platform to process and store digital information and transactions using special secure cryptology techniques based on the elliptic curves digital signature algorithm (ECDSA). It is reported that this technology is worth \$630 billion a year industry with an annual growth of 7%. The implementation of blockchain has a promising future represented in saving million working hours per annum, saving more million printed documents annually, saving around billion dollars in transactions and ensuring the digital security of national and international documents and transactions.

Therefore, blockchain is a promising ledger which can be used as a new platform for digital information and to store encrypted data and process secure digital transactions. This blockchain possess strong features that enable users to store sensitive personal data and financial credentials. But it happened that many reports that claim bitcoin wallets have hacked and led into losing investments. Therefore, this chapter proposed a multi-layer encryption technique along with artificial intelligent neural networks codes to be implemented to enhance the encrypted data and security characteristics. In particular, AINN Machine learning can be very effective in hashing algorithms of mining transactions blocks of Bitcoin blockchain platform compared to a tedious time consuming tradition approach. In order to protect personal data and information as third wall defense against hacking, the utilization of pretrained convolutional neural network (CNN) is proposed to be a part of the block chain. CCN is used to extract learned image features and use those features to train an image classifier with single pass making advantage of machine learning tools features. Simulation results demonstrates the effectiveness of using pre-trained CNN blockchain-based information. In particular processing and classification of document and images of 6 different categories are 100% efficient to classify fingerprints, ID cards, passports, bank cards, bank statements, and bitcoin transactions.

This new innovative technology has its own advantages and disadvantages that receives some supports as well as some concerns. Advantages of the Blockchain Technology:

- Zero Percentage of Fraud;
- Non-centralized Process;
- Instant Transactions;
- Improved Financial Efficiency.

Disadvantages of the Blockchain Technology:

- Digital black market;
- Non-Tangible and Extremely Volatile;
- High Tech for Traditional Customers or Operations.

In overall, this chapter introduces a novel integrated cryptology approach of artificial intelligence based blockchain by introducing a multilayer security layer and neural networks machine learning techniques. Specifically, this revolutionary safe combination criteria is structured by implementing a coupled private key elliptic curves digital signature in order to securely enter into the blockchain and process encrypted data using neural networks. By the virtue of this algorithm and by using blockchain and AI network service will provide users, owners and organizations with security measures needed to ensure that their data is safe from attacks and siphoning. Moreover, this will provide business enterprises with blockchain technology to prevent any attempts by hackers to conduct cyber-attacks.

KEY TERMS AND DEFINITIONS

Bitcoin: Invented in 2008 by Satoshi Nakamoto to create a decentralized digital currency used to record peer-to-peer transactions generated by complicated mathematical models to ensure security without the need for intermediaries such as central banks.

Blockchain: A system made-up of blocks that are used to record transactions in a peer-to-peer cryptocurrency network such as bitcoins.

Convolutional Neural Networks (CNN): A special type of neural networks used popularly to analyze photography and imagery.

Cryptology: A technique used to secure communicating of information, data and messages by implementing special protocols and algorithms aims to prevent other parties from reading and understanding the information transmitted.

Digital Signature: A secure mathematical algorithm used to validate the credentials of digital documents and coded information associated with pre-approved signer to approve transactions.

Elliptic Curves Digital Signature Algorithm (ECDSA): Is a mathematical cryptology technique used by digital currencies and Bitcoin to ensure the security of the peer-to-peer transactions using secret codes and keys.

Encryption-Decryption: An algorithm used to transform information to something random, meaningless and not readable, and then translate it back to something understandable.

Singular Value Decomposition (SVD): A factorization mathematical algorithm of matrices used in diverse application such as signal processing, communication, and imagery.

An IBE–Based Authenticated Key Transfer Protocol on Elliptic Curves

INTRODUCTION

The twentieth century grew with the rapid development in the area of Internet and Mobile Communications Technologies/Applications, called Information and Communication Technology (ICT). ICT services have grown exponentially and become beneficial to the world in different ways. However, these technologies are changing very frequently, and several services with multimedia applications are growing through various real-life applications. In these regards, the security protection to various services becomes essential and challenging as well, and different security mechanism for different encryption, authentication, and integrity easy data availability technologies are being developed in a rapid pace. In order to design different security mechanisms and meet the challenges, different cryptographic primitives are used in their convenient ways. In the era of Internet technology; key transfer protocols are playing a crucial role in the network and information security field. These protocols are mainly incorporated to transfer a common session key among different user. The key exchanged using these protocols is generally used for symmetric key encryption where this key is known as private key and used for both encryption as well as decryption. As we all know, many key transfer protocols including basic Diffie-Hellman protocol, are proposed in the literature. However, many of these key transfer protocols either are proven insecure or had a burden of communication and computational cost. Therefore, a more secure and efficient key transfer protocol is needed. In this paper, the author proposes an authenticated key transfer protocol, which securely and efficiently negotiates a common session key between two end users. He calls this protocol as IBE-TP-AKE. This proposal is based on the elliptic-curve cryptography (ECC) and uses the idea of identity-based encryption (IBE) with pairing. The security of the proposed work is based on the hard problems of elliptic curve and their pairing extensions discussed in Gupta & Biswas (2015a), Gupta & Biswas (2015c) etc. Further, the author has shown the security of his proposed protocol and proved it using the security properties discussed later. All security properties of key exchange protocol is possessed by our proposed protocol. As we know, cryptography is a branch of science and it is an art to use security primitives in a way to deal with the security challenges and meet the solutions. Data encryption in cryptography is divided into two major categories namely, symmetric/private-key and asymmetric/public-key techniques in which the latter one has greater research impact than the former. However, the useful public-key cryptographic techniques like RSA, ElGamal etc. have some disadvantage as they require extensive public key management overheads. Thus, new technique called, identity-based encryption (IBE) is introduced recently and is used by researchers to design efficient cryptographic tools for different security applications. In this article, the author has formulated the idea of this technique to implement his protocol. Shamir (1984) has firstly proposed the novel idea of IBE by choosing the known identity of a user as public-key. This known identity may be Email, Ph. No, IP address etc. Using the

DOI: 10.4018/978-1-5225-9715-5.ch076

identity of a user as public-key, Shamir removed the overhead of certificate management from public-key cryptography. In addition, a trusted third party Private Key Generator (PKG) is considered to generate user's private key. However, the practical implementation of IBE is considered in Boneh & Franklin (2001). This proposed IBE-TP-AKE protocol includes the properties of a pairing technique as defined in Gupta & Biswas (2015b). This bilinear map relates two members of a group to a member of another group. For this particular paper, a bilinear mapping technique takes two members (points) of an elliptic curve group and maps it to a member of another multiplicative group. However, authentication to our proposed IBE-TP-AKE scheme is provided by means of the ECC. The elliptic curve hard assumptions are the hard problems which are used to efficiently secure the presented protocol. The security provided by the ECC is efficient than that of RSA. A 160-bit key in ECC provides the same level of security provided by a 1024-bit key size in RSA as Gupta & Biswas (2017). The points of the elliptic curve group generate an abelian group which is used to generate the cryptographic algorithms.

BACKGROUND

Diffie and Hellman (1976) were the first who gave a new idea of having two separate keys; one for encipherment and other for decipherment. This proposal gave the birth to the key exchange protocol which is named as Diffie and Hellman (DH) key exchange protocol. Their idea was to exchange a common secret key between two authentic entities. But unfortunately, their proposal is vulnerable to a number of attacks which includes well known man-in-the-middle (MITM) attack. To eliminate these difficulties, research has grown in this direction and many researchers have proposed different type of key transfer protocols like Liu et al. (2012), Gupta & Biswas (2016), Gupta & Biswas (2017a), Cheng et al. (2013), Gupta et al. (2018a) etc. Jeong et al. (2004) designed many two party key agreement protocols which are executed in one round of communication. They claim that the proposed protocols are authenticated and resist many attacks. McCullagh & Barreto (2005) proposed a key agreement protocol for two parties which were developed in IBE framework. They showed that their protocol is efficient and secure than other existed state-of-the-arts. They also presented the comparative analysis for their proposed key agreement scheme. Choo (2005) reviewed McCullagh & Barreto (2005) and showed that their protocols are vulnerable if the attacker has sent the *Reveal* query. Hölbl et al. (2012) devised an identity-based key exchange scheme for two parties. For their proposal, they used the pairing technique and also derived a variant of signature schemes which confirms the security of their proposal. They also claimed that their protocol is comparatively secure and cost efficient. Gupta & Biswas (2017b) proposed two secure bi-partite key agreement protocols using the IBE and pairing. The first protocol is based on the DH key agreement protocol; however the later is based on the elliptic curve group. They further extended their two party key exchange protocol for three party key exchange protocols. They showed that their protocols are secure against many attacks and claimed that these protocols exhibit better security and efficiency than other similar literatures. Tseng (2007) proposed an identity based key agreement protocol based on the hard problem of discrete logarithm. It was claimed that the computation and communication cost of his protocol is better than other competing protocols. His protocol is secure and resistance to many possible attacks. Gupta & Biswas (2018b) devised two authenticated key exchange protocol using signature and signcryption authenticators. The security of their protocols is based on the lattice hard problems. They claimed that their protocols resist the quantum attack.

TECHNICAL TERMS AND DEFINITIONS

Moreover, the definitions and notations used in the development of this paper is considered and explained below:

Elliptic Curve Cryptography (ECC): Miller (1985) firstly introduced the concept of an elliptic curve cryptosystem. By using ECC, he designed a key agreement protocol which is similar to DH key agreement protocol. Later, Koblitz (1987) also proposed a cryptosystem based on the elliptic curve. A cryptographic elliptic curve of prime order p is denoted by E/F_p and is expressed as the following equation:

$$y^2 = x^3 + ax + b$$

In the above equation, a and b are the elements of F_p and satisfies the relation $4a^3 + 27b^2 \neq 0$. All the points of elliptic curve forms an additive group with commutative operation. This “+” operation on points is defined as follows:

Let the two point of an additive group E/F_p be L and T . The addition of points L and T can be calculated as following conditions:

- Let these two points L and T are different point on the curve having different x and y coordinates and the line joining these two points cuts the curve on another point $-Y$, then the image of $-Y$ about x -axis gives the addition $L+T$ i.e. $Y=L+T$. Here, the points Y and $-Y$ are known to inverse to each other with respect to elliptic curves.
- Let these two points L and T overlaps i.e. $L=T$. In this case, the line joining these same points will be the tangent to the curve and let it cuts the curve on a point $-Y$, then the image of $-Y$ about x -axis gives the addition $L+T$ i.e. $Y=L+L=2L$ or $2T$.
- Let two points to be added are inverse to each other i.e. the points on the curve are L and $-L$, thus the line joining these points cuts the elliptic curve at Infinity called point of Infinity and denoted by O . Thus the addition is $L + (-L) = O$. The point of infinity is the identity of elliptic curve.
- The scalar multiplication on the elliptic curve can be calculated by adding the same point scalar times i.e. kL can be calculated by adding L using the above rules, k time.

Bilinear Mapping: The technique of bilinear mapping is mainly used in the IBE to pair two groups of same order. In recent years, bilinear pairing has played an essential role in designing many cryptographic primitives. Let there are two groups namely G_1 and G_2 both having the same order q where q belongs to a number from prime set. The group G_1 is considered as an elliptic curve group, whereas group G_2 is a multiplicative group of same order. A bilinear mapping is denoted by $\hat{e}: G_1 \times G_1 \rightarrow G_2$ which maps two elements of G_1 to an element in G_2 and defined by these three properties:

- **Bilinearity:** This property executes $\hat{e}(lL, tT) = \hat{e}(L, T)^{lt}$ for all $L, T \in G_1$ and $l, t \in \mathbb{Z}_q^*$.
- **Non-Degeneracy:** This property tells that the mapping does not map all pairs in $G_1 \times G_1$ to the identity element in G_2 .
- **Computability:** The bilinear mapping $\hat{e}(L, T)$ can be efficiently computed for $L, T \in G_1$.

Further, it can be easily seen that the bilinear operation exhibits the commutative property i.e. $\hat{e}(L, T) = \hat{e}(T, L)$.

Identity-based Encryption: The public-key encryption (PKE) scheme involves a lot of overhead in the certificate management. Further, a public-key certificate is also need to be verified by the user for the validation of the public key. To eliminate the overhead of certificate management in the classical PKE, as early as 1984, Shamir (1984) firstly gave an idea about a PKE scheme where an identity of the user is treated as the public-key and it is named as Identity-based Encryption (IBE). This was the original motivation for IBE. In IBE, the public-key can be any arbitrary string and a sender may use an identity (say ID) of the receiver for encryption of the messages. For instance, when Alice sends a message to Bob, she encrypts her message using the Bob's public identity as email address "bob@ domainname. com". Then, Bob can decrypt the message using a private key taken securely from private key generator (PKG) through proper authentication. This novel concept of Shamir's proposal initiates a paradigm shift in public-key cryptographic techniques. However, until the year 2001, it was an open challenge for the researchers to construct a fully functional and efficient IBE. Boneh & Franklin (2001) firstly proposed a fully functional IBE from the Weil Pairing. The IBE scheme mainly depends on a trusted authority, called PKG who generates the global system parameter *param* and the secret key for the users according to their public identity. IBE comprises four randomized algorithms namely, *setup*, *extract*, *encrypt* and *decrypt*. The generated private-key is transferred to the data user via a secure channel. With the nice functionality that any party can perform the encryptions of messages with no prior keys distribution among individual parties, IBE gains lots of attention from industry, research and academic community. The four algorithms of IBE are as follows:

- **Setup:** This algorithm is used to generate the system parameters *param* and executed by a third party PKG. The input to Setup algorithm is a security parameter *t* and the output is generated *param* including the master secret of PKG.
- **Extract:** This algorithm is used for key extraction and also executed by PKG. The input to Extract algorithm is the identity ID of a user and the output is private key of the user. The PKG securely transmits private key to its owner.
- **Encrypt:** This algorithm is run by the sender of a message *m*. The input to Encrypt algorithm is a message *m* and the output is the encrypted message, called cipher text generated using the *param*.
- **Decrypt:** This algorithm is run by the receiver for decryption of the cipher text. The input to Decrypt algorithm is cipher text and output is plain text message recovered using the private key of receiver.

Security properties: The security properties of any key agreement protocols must be protected from an adversary. An adversary can attack on the key exchange protocol in many ways to breach its security. Thus, the development of key exchange protocols should be done in very careful manner so that the designed key must resist all the possible types of attack. For designing a secure key, some security properties must be defined as described in the Bellare & Rogaway (1993). Let P_1 and P_2 be two authentic users. The following security properties must be possessed by the proposed IBE-TP-AKE protocol:

- **Man-in-the-Middle (MITM) Attack:** This attack is very well known attack. An attacker impersonates both the authentic entities to exchange two different keys with them. One key is used with a user and another is used another user.
- **Known Key Security:** This security confirms that if session keys which are negotiated in previous rounds are compromised to the adversary then the current round key must not be compromised i.e. the session keys which are executed in the current round should be independent to other rounds keys.

- **Key Control:** Any authentic user can not be able to generate the session key individually. To generate the correct session secret key, the involvement of both the users is compulsory.
- **Unknown Key-Share Resilience:** In this security, it is believed that a user P_1 is not negotiating a session key with a third party called, adversary instead of P_2 while P_2 believes that the key is shared with him and P_1 .
- **Perfect Forward Secrecy:** In this security, it is believed that if private keys of any or all users are known to the adversary, then the adversary cannot get the previously generated session keys with the help of these private keys.
- **Key-Compromise Impersonation Resilience:** In this security, it is desired that if the private key of a user say P_1 is compromised by the adversary, then the adversary cannot impersonate the other user P_2 . It is obvious that adversary can impersonate P_1 easily because he knows the private key.

Computational Problems: Some computational hard assumptions are laid here:

- **Discrete Logarithm Problem (DLP):** This hard problem states that if a and b are taken from a multiplicative group i.e. $a, b \in G_2$ and a and b are known where $b = a^r \mod q$ for all $r \in \mathbb{Z}_q^*$, then it is hard to find the value of r .
- **Elliptic Curve Discrete Logarithm Problem (ECDLP):** This hard problem states that if L and T are taken from an additive group i.e. $L, T \in G_1$ and L and T are known where $T = rL$ for all $r \in \mathbb{Z}_q^*$, then it is hard to find the value of r .
- **Bilinear Diffie-Hellman Problem (BDHP):** This hard problem states that if L is taken from an additive group i.e. $L \in G_1$ and L, xL, yL and zL are known where $x, y, z \in \mathbb{Z}_q^*$, then it is hard to find $\hat{e}(L, L)^{xyz}$.
- **Computational Diffie-Hellman problem (CDHP):** This hard problem states that if L is taken from an additive group i.e. $L \in G_1$ and L, xL and yL are known where $x, y \in \mathbb{Z}_q^*$, then it is hard to find xyL .

PROPOSED IBE-TP-AKE PROTOCOL

In this section, the designed IBE-TP-AKE protocol is laid down. This proposed protocol is developed using IBE framework. In this protocol, security of negotiated key and authentication of users are ensured using the different hard assumptions as discussed earlier. However, the computational as well as communication complexities are also reasonable. Suppose the sender S wants to negotiate a common secret key with the receiver R . Except the sender and receiver, a third entity PKG is also involved in the protocol. The phases of proposed IBE-TP-AKE protocol are described as following steps:

1. **Initialization Phase:** The initialization phase of the proposed protocol consists of following algorithms as IBE discussed earlier:
 - a. **Setup:** This algorithm of the proposed IBE-TP-AKE protocol is executed by PKG and it take a security parameter t as input and generates the following parameters:
 - i. A t -bit prime number q and two q order groups G_1 and G_2 in which group G_1 is considered as an additive elliptic curve group, whereas group G_2 is a multiplicative group of same order.
 - ii. A bilinear pairing $\hat{e}: G_1 \times G_1 \rightarrow G_2$.

- iii. A primitive element P in G_1 and a generator g in G_2 .
- iv. Two hash functions (cryptographic) H_1 and H_2 defined as $H_1: \{0, 1\}^* \rightarrow G_1$ and $H_2: G_2 \rightarrow \{0, 1\}^q$.
- v. A master secret s which is secret to the PKG and master public key $P_{pk} = sP$.

PKG publically announces system parameters $param = \{q, H_1, H_2, G_1, G_2, P, \hat{e}, P_{pk}\}$ and kept master secret as private to itself.

- b. **Key Extraction:** This algorithm of the proposed IBE-TP-AKE protocol is also executed by PKG to extract the private key of users S and R . The PKG executes these steps:
 - i. The users request the PKG with their identities ID_i for $\{i=S, R\}$.
 - ii. PKG checks the authenticity of the users S and R and calculates their private keys as P_{pri} as $P_{pri} = sQ_i$ for $\{i=S, R\}$. Here, $Q_i = H_1(ID_i)$.
 - iii. The public keys of the users are Q_i . It may be noticed that there is no need of public key certificates to verify the public key of users.
- 2. **Key Exchange Phase:** In this phase, the users S and R negotiate a common secret key between them. Let, S is the initiator and R is the responder of the proposed IBE-TP-AKE protocol. The steps used to exchange the secret key are as follows:
 - c. User P_1 initiates the protocol and does the followings:
 - i. Selects a random integer $a \in Z^*$. P_1 then computes the key related message as $u = g^a \mod q$.
 - ii. Calculates $\mu_s = \hat{e}(P_{pri_s}, X_s)$ using his private key P_{pri_s} where $X_s = aP$.
 - iii. Computes $\sigma_s = u \oplus H_2(\mu_s)$ and sends $Y_s = aQ_s$, u and σ_s to P_2 .
 - d. After receiving the messages, user P_2 responds in the following manner:
 - i. Computes $\gamma_r = H_2(\hat{e}(Y_s, P_{pk}))$ and checks $u = ? \sigma_s \oplus \gamma_r$. If the verification is true then P_2 picks a random integer $b \in Z^*$ and computes common secret key K_2 as $u^b \mod q$. Thus, the computed key $K_2 = g^{ab} \mod q$.
 - ii. Computes the key related message $v = g^b \mod q$.
 - iii. Calculates $\mu_r = \hat{e}(P_{pri_r}, X_r)$ using his private key P_{pri_r} where $X_r = bP$.
 - iv. Computes $\sigma_r = v \oplus H_2(\mu_r)$ and sends $Y_r = bQ_r$, v and σ_r to P_1 .
 - e. Finally after receiving the messages, P_1 computes $\gamma_s = H_2(\hat{e}(Y_r, P_{pk}))$ and checks $v = ? \sigma_r \oplus \gamma_s$. If the verification is true then computes common secret key K_1 as $v^a \mod q$. Thus, the computed key $K_1 = g^{ab} \mod q$.

Thus, it may be easily seen that $K_1 = K_2 = g^{ab} \mod q$. Note that the proposed protocol executes in only one round of communication and the proof of the verification $v = ? \sigma_r \oplus \gamma_s$ (and the proof of $u = ? \sigma_s \oplus \gamma_r$ is similar) is given below.

Since

$$\begin{aligned}
 \sigma_r \oplus \gamma_s &= v \oplus H_2(\mu_r) \oplus \gamma_s \\
 &= v \oplus H_2(\hat{e}(P_{pr}, X_r)) \oplus H_2(\hat{e}(Y_r, P_{pk})) \\
 &= v \oplus H_2(\hat{e}(sQ_r, bP)) \oplus H_2(\hat{e}(bQ_r, sP)) \\
 &= v \oplus H_2(\hat{e}(Q_r, P)^{bs}) \oplus H_2(\hat{e}(Q_r, P)^{bs})
 \end{aligned}$$

= v (Proved)

SECURITY ANALYSIS OF PROPOSED IBE-TP-AKE PROTOCOL

This section comes with the security analysis of our proposed IBE-TP-AKE protocol. Our presented protocol resists all possible security attacks which can be used to breach the security of a key exchange protocol. The different type of security attacks are discussed below and it has been proved that our proposed IBE-TP-AKE protocol is secure against all these type of attacks.

1. **Man-in-the-Middle (MITM) Attack:** Our proposed IBE-TP-AKE protocol negotiates a common secret key and security of this key is provided using the signature σ_i for $i = s, r$ of individual users. In our protocol, users S and R generates the signatures σ_s and σ_r using their private keys respectively. If an adversary $\hat{A}$ tries to impersonate any of the authentic users S and R, she cannot generate a valid signature and thus it is difficult for $\hat{A}$ to impersonate S and R. Hence, our IBE-TP-AKE protocol is not vulnerable to MITM attack.
2. **Known Key Security (K-KS):** In our protocol, the negotiated secret key K in each session is unique because the secret key K is generated using the ephemeral secret values a and b chosen by users S and R at random. Thus, if adversary $\hat{A}$ has the access to previous session secret keys, she might not be able to derive the current or future session keys. Thus, K-KS attack is resisted by our protocol.
3. **No Key Control (NKC):** A single user in our protocol cannot derive the correct session key because both ephemerals a and b are not known to him. It is necessary for our proposed protocol that both S and R must be involved in the process of generating the session secret key. An individual user cannot enforce the correct key K. Thus, the proposed key exchange protocol is free from NKC attack.
4. **Unknown Key-Share (UK-S) Resilience:** The proposed protocol requires the private keys P_{pri} and identities ID_i for $i = s, r$ of users S and R to generate the signature σ_i . Adversary $\hat{A}$ cannot generate the valid signature σ_i which can be verified by the authentic parties S and R. Thus, it is not possible by a user either S or R to share a correct key with $\hat{A}$. Hence, our proposed protocol resists UK-S attack.
5. **Perfect Forward Secrecy (PKS):** The adversary $\hat{A}$ cannot recover the previous session keys even after getting the private keys P_{pri} for $i = s, r$ of all authentic users S and R because in the process of key generation the ephemeral secrets a and b which are chosen at random by S and R. It is difficult for $\hat{A}$ to recover a and b from $g^a \bmod q$ and $g^b \bmod q$ respectively because of DLP. Thus, the proposed protocol follows PKS.

6. *Key-compromise impersonation (K-CI) resilience:* In this type of attack, the adversary $\hat{A}$ somehow get the private key of one user, say P_{prs} of user S . Now, $\hat{A}$ tries to impersonate R to S but she is not able to do so because she do not know the private key $P_{pr\hat{r}}$ of another user R . Thus, K-CI attack is prevented by out IBE-TP-AKE protocol.

FUTURE RESEARCH DIRECTIONS

The key exchange protocols play a vital role in design of cryptographic protocols either symmetric or asymmetric. This chapter executed a key exchange protocol which is secure and efficient. However, more secure and efficient key exchange protocols are needed for the different type of lightweight applications. The authors considered these novel protocols as open problem. Further, the quantum computer may exist in future and it is believed that the classical hard assumption may be broken by the quantum computer. Thus, there is a need of key exchange protocols which can resist the quantum attack. This problem of developing quantum free key exchange protocol is also supposed to be open.

CONCLUSION

A novel and efficient authenticated key agreement protocol is devised in this chapter. The proposed key agreement protocol is executed for two users and the negotiated key is shared between both the users. For development of key exchange protocol, the author has used the concept of IBE and bilinear pairing. The security of the proposed protocol is ensured using the hard assumptions of elliptic curve as well as DLP. Further, the security of proposed IBE-TP-AKE protocol is analyzed in the view of all its security properties. The author has proved the security proofs of proposed protocol. Author has given the open problems related to key agreement schemes.

KEY TERMS AND DEFINITIONS

Authentication: Permission to access something, which is confidential. The authentication is only provided to authentic users.

Cryptography: The art and science of creating unreadable messages from readable messages by the need of security.

Decipherment: The inverse of encipherment which is also an algorithm to change unreadable messages to readable messages.

Elliptic Curve: A curve in two dimensions, which is known by its group property on points. It is widely used in cryptography due to its hard assumptions.

Encipherment: An algorithm used to convert a readable message into unreadable message. It is used in the field of security.

Key Exchange: A method of transferring a secret key among various users. This key may be needed in cryptography to protect many entities like information, system, etc.

Secure Communication: A method of transferring information on the internet securely.

Efficiency Issues and Improving Implementation of Keystroke Biometric Systems

INTRODUCTION

Employees use more and more their mobile devices in work specifically after having introduced a new trend called BYOD (Bring Your Own Devices) that allows workers to provide their own devices and use the same materials for both personal and professional purposes. This new practice improves employee productivity by using of a mastered mobile device and it decreases the budget spent on IT because the materials used are purchased and maintained by employees at the same time it offers disadvantages like security issues. Therefore, it is very important to use an authentication platform like authentication based on knowledge (password, etc.), physical biometric authentication (iris, etc.) or behavioral biometric authentication (keystroke dynamics, etc.) to avoid data leakage.

This paper deals with biometric authentication based on keystroke dynamics. The method consists of analyzing the typing patterns of a claimed user and then decide to accept or reject the user authentication attempt.

The main advantages of keystroke dynamics are: (1) it improves productivity by using a known device, (2) As the user is typing his login and password; biometric data is extracted and compared to a reference profile stored in the system database without the need of an extra time to verify the user, (3) it allows a reduction in investment, it does not require external hardware. The keystroke dynamics implementation is based essentially on software, which is the subject of this paper.

keystroke can be integrated into several applications, whether web applications, behavioral intrusion detection system, online banking, etc. Its flexibility comes from the fact that the administrators of its systems do not have to force the user to buy additional equipment (e.g fingerprint capture, iris capture, voice capture, etc.) to read the end user's biometric data.

The paper sections are organized as follows: the first section is the methodology followed in the article where we presented the keystroke dynamics technique with its characteristics and the sensors used in the software (dwell time and digraph time). In the same section, we also mentioned some real-world application of this technique and finally the architecture adopted in the development of the software. The second section is the proposed work in which the four phases (registration, enrollment, authentication and classification) have been detailed. We then treated the setting part and the error metrics that we will use to test the accuracy of the software.

DOI: 10.4018/978-1-5225-9715-5.ch077

BACKGROUND

Keystroke dynamics was and remains a strong field for research, the first documented research published by Forsen, Nelson and Staron (1977) dated back to 1977. Later, many other papers were appeared. For instance, Patil and Renke (2016) published a paper where they better cleared up keystroke dynamics, they mentioned some drawback of this biometric method and they distinguished two different keystroke dynamics authentications: static and continuous. In static, the user is asked to type his login and password, then he is validated by comparing those data with his pre-calculated profile. In the continuous authentication, the end-user's biometric data is captured throughout the use of the system. The use of the second kind of authentication prevents an impostor from taking control of the machine when its legal user is absent (several users leave their workstations without locking them or putting them in sleep mode). In this case keystroke recognition can be used as a behavioral intrusion detection system. Grant Pannell and Helen Ashman (2010) combined a set of factors including CPU usage, sites visited and keystroke biometric to implement a behavioral IDS to detect unauthorized users through their system usage. On the same page, Avasthi and Sanwal (2016) gave the existing approaches, security and challenges of keystroke dynamics in order to motivate the researches to further come with more innovative improvements. Some other researchers like Panasiuk, Dabrowski, Saeed, and Bochenska-Wlostowska (2014) devoted their studies to compare different keystroke dynamics databases and to test if the same algorithm running on two theoretically identical databases gives the same results.

Other research tried to improve the EER (Error Equal Rate) and the security level of the devices using keystroke biometric like Morales, Falanga, Fierrez, Sansone, and OrtegaGarcia (2015) team and Nagargoje, Lomte, Auti, and Rokade (2014) team who combined keystroke and mouse movement to authenticate the user and increase the device confidentiality.

Systems with touchscreens, which are replacing more and more traditional computer systems, arouse researchers like Kambourakis, Damopoulos, Papamartzivanos, and Pavlidakis (2014). They try to adapt keystroke dynamics authentication to this kind of screen. Teh, Zhang, Teoh, and Chen (2016) gave us an overview and survey of a touch dynamics authentication system available for devices with touchscreen.

Morales, Fierrez and Tolosana (2016) focused on reporting the results of 31 different algorithms evaluated according to accuracy and robustness.

Liakat, Monaco, Tappert and Qiu (2017) presented a detailed survey of the most recent researches on keystroke dynamic authentication. They analyzed different methods, algorithms used, the accuracy rate, and the shortcomings of those investigations. In the same direction, Teh, Zhang, Teoh and Chen (2016) presented a survey of user authentication using keystroke dynamics.

Further, new studies are focused on analyzing keystroke recognition method for smartphones such as Ho's research published in 2014 and later Alzubaidi and Kalita in 2015, they highlight some problems that concern smartphones security in fact that smartphones are small in size and they can easily be lost or be stolen which increases the need to use two-factor authentication. Different research has shown that keystroke dynamics can be adapted to different systems. For example, Antal, Szabo, and László (2015) demonstrated experimentally, using Android devices, that touchscreen-based features improve keystroke dynamics based identification and verification. Boakye and Marfo (2016) determined the effectiveness of keystroke analysis and password security synergy to authenticate users of a system web-based applications. Another example to give is Babaeizadeh, Bakhtiari, and Maarof (2014) who address using keystroke authentication in mobile cloud computing.

Our Contribution

1. Most available software in keystroke dynamics fields use Euclidean distance in their algorithm. However, according to the team research composed of Panasiuk, Dabrowski, Saeed, and Bochenska-Wlostowska(2014) and the team composed of Antal, Szabo, and László (2015), k-Nearest Neighbor (K-NN) and Manhattan distance are the most top-performing methods comparing with the Euclidean distance. Which makes the software using the last method less precise and the results obtained less exact.

Thus, to improve the keystroke algorithm, we use k-Nearest Neighbor (K-NN) as a classification method. KNN, a straightforward classifier, has been used in statistical estimation and pattern recognition. It identifies the k closest neighbors of feature value. In our case, we use 1-NN to search one nearest neighbor of a user's typing pattern.

In addition, we adopt K-NN and K-FN (K-Further Neighbor) algorithm based on Manhattan distance instead Euclidean distance to calculate the distance between the claimed user typing pattern and the original user feature values.

2. Most research remains theoretical. In this paper, we propose a complete software that can be used in mobile devices that need a biometric system for authentication besides password especially devices without two-factor authentication method. The software is based on the pseudo code already discussed in our previous paper Jaha and Kartit (2017).

METHODOLOGY

Keystroke Dynamics

The authentication process validates the identity of the user who is trying to connect to the system. Most traditional systems are based on a login and password to grant or not access to the device whether it is a computer, smartphone, e-mail, cloud or e-commerce. This kind of authentication belongs to the category of knowledge-based authentication. For companies and information technology systems, whose data is sensitive, critical and does not support identity theft or data leakage, the use of single-factor authentication such as password-based authentication can cause them many security problems. Thus, they use more sophisticated authentication methods such as ownership-based authentication (e.g access card), and biometric-based authentication (e.g keystroke dynamics).

The biometric-based authentication divided into two parts: physiological such as fingerprint identification and retina scan, and behavioral like voice recognition and keystroke dynamics recognition. To choose the appropriate authentication method, the IT system administrator can refer to the following criteria:

- The IT budget.
- The level of security that the administrator wants to apply in the company (high, medium, low).

Keystroke recognition is a biometric technique which can automatically identify a person by typing his login and password. It describes exactly when each key was pressed and when it was released the time a device user is typing.

We chose keystroke biometric because of its many characteristics, including:

- **Uniqueness:** Each of us has his own way of typing that differs from another person so even if another user has discovered the password via hacking techniques such as brute force attack or shoulder surfing attack. the password will be useless to him because the two users have two different typing profiles.
- **Reduced Cost:** We do not need to buy an external device we just need the keyboard and software that captures the user's biometric information unlike other methods that require an external device.
- **Simplicity of implementation:** to implement Keystroke dynamics we need to capture and save the user's biometric data and save his typing profile. many algorithms are used to implement keystroke such as the example of a CREYC algorithm based on Euclidean distance and the algorithm discussed in this paper based on K-NN and Manhattan distance. The most important thing is that the code is feasible and can be integrated into different applications requiring authentication such as windows applications, web applications, social networks, online banking, e-commerce, etc.
- **Easy Updating:** Keystroke dynamic changes with age or after some diseases in this case just ask the user to retype his login and password to capture his new biometric data.

There are many keyboard features can be used to authenticate a person using typing pattern: keystroke pressure, keystroke speed, typing sound, dwell time and flight time.

Studies conducted by Kaur and Virk in 2013 and those of Morales, Fierrez, Tolosana, Ortega-Garcia, Galbally, Gomez-Barrero, ... and Marcel in 2016 demonstrate that the use of dwell time and digraph times (flight times) gives the best FAR (False Acceptance Rate) and FRR (False Rejection Rate) combination. Therefore, for identifying the genuine user from impostors, we have adopted dwell time noted f_i^d and different digraph times noted f_i^{L1} , f_i^{L2} and f_i^{L3} in which:

- f_i^d : Is the time interval between consecutive key press and key release
- f_i^{L1} : Is the time difference between releasing the i th key and pressing the $(i+1)$ th key.
- f_i^{L2} : Is the time difference between the pressure of the i th button and pressure the $(i+1)$ th button.
- f_i^{L3} : Is the time difference between the release of the i th key and the release of $(i+1)$ th key.

Real-World Applications of Keystroke Dynamics

The first application field of keystroke dynamics is security. Keystroke dynamics allows us to adopt two-factor authentication by combining the knowledge-based authentication and biometric-based authentication. One of the advantages of this technique is that the system administrator will not have to create and apply a password policy to force the user to change his password after a certain period of use and the employees can keep the same passwords. they can also use weak passwords without respecting the password complexity requirements without creating a vulnerability in the IT system (the hacker, even if he knows the password, must simulate the typing profile of his victim).

Besides using keystroke dynamics to authenticate a system user in order to increase the level of security and filter out unauthorized users, the application areas for dynamic typing remain numerous and varied.

The keystroke recognition approach can be used in the field of medicine as illustrated in very interesting paper published by Adams W. R. (2017). In this paper, he discussed the possibility of using keystroke

dynamics for the early detection of Parkinson's disease. The study collected biometric data from people who are affected by Parkinson's disease and from other healthy people. The dataset is analyzed and then transformed into graphs to determine a predicted probability. The same concept is applied by other research conducted by Arroyo-Gallego, T., Ledesma-Carbayo, M. J., Sánchez-Ferro, A., Butterworth, I., Mendoza, C. S., Matarazzo, M., ..., and Giancardo, L. (2017). the latest research focused on early detection of the disease using this time the touch screen instead of keyboard. The most important thing that can be deduced from these studies is that the patient can know if there is a probability of being affected without medical assistance and without the need for external equipment.

Keystroke dynamics recognition as a behavioral-based authentication, several researchers have integrated the method into behavioral intrusion detection system. Grant Pannell and Helen Ashman (2010) proposed an IDS that combines several factors (mentioned above) including keystroke biometric. the IDS makes it possible to detect abnormal manipulations of the system. the research proposes an H-IDS (host-based intrusion detection) that is installed on each machine to detect usage violations. Similarly, Bondada, M. B. and Bhanu S. M. S. (2014) proposed using an IDS based on keystroke dynamics to detect identity theft and criminal activity that a cloud can be exposed to.

Proposed Work Architecture

Figure 1 shows the general approach used in this study. During his first access to the computer system, the user has to create his own account (Registration phase) and then he is asked to type his login and his password n times (enrollment phase). As the user types, the system records his biometric features (features collection) and stores his reference profile in the system database.

At every attempt of connection to the system, the software captures and recalculates the keystroke biometric of claimed user (authentication phase). This phase involves the use of a classification method; we have used KNN with Manhattan distance, to compare new data against the recorded signature (classification phase). Then, the user will be accepted or rejected based on a predetermined threshold value.

Figure 1. Keystroke dynamics architecture

PROPOSED WORK

We transformed the theoretical framework discussed above to a software divided on different windows, each of them presents one of the phases quoted in the methodology section. The code is written in C# using Microsoft Studio 2015 and we evaluated and analyzed the software using laptop keyboard.

Registration

The registration process is the first step to accomplish before reaching other phases. The user must fill some information including, his full name, his login and password that will be used to authenticate to the system, his gender, his date of birth, and his full address. The account created will be used in authentication and enrollment phases. Those Data will be stored in the system database for future use.

Enrollment Phase and Features Collection

The next step is enrollment phase; the user clicks on the enrollment button to begin the features collection process. Most research capture features data for user password only, in our software we propose to record biometric data during all identification and authentication processes in order to increase the extracted features which means more accuracy. Figure 2 is a screenshot demonstration of user biometric data; the password tested is “ensajschool”.

The user must type his login and password several times. Enrollment attempts is determined by the administrator. In our example, we have chosen 20 as the number of enrollment attempts. The system administrator can increase or decrease the value in setting window.

While the user is typing on keyboard for submitting samples, the software records when keys were pressed and were released to calculate user features like dwell time, digraph time 1, digraph time 2 and digraph time 3. The stored profile will be noted "fg" for genuine user and it represents the reference profile that we will use in classification phase.

Typing login and password containing letters and digits required pressing letters, digits and special keys (tab key to move cursor to the password textbox, caps lock key or shift key to type digits and del or backspace in case of error). By default, the software collects the time functions of all keys, including special keys such as: tab, shift, del, backspace, caps lock... Which gives a false length of typed data. The length value is an essential parameter for a good functioning of the algorithm. That's why we configured the software to ignore these keys.

Figure 2 shows different graphs for dwell time and digraph times, we record those function for the 17 logins and password keys.

Authentication

Each access to the system requires an identification and authentication. Identification allows answering the question: “Who are you?”. It is a phase of establishing the identity of the user. The user uses an identifier called “username” or “login” that identifies and assigned to him individually. Authentication intervenes after the so-called identification phase. It is a phase that allows the user to provide proof of identity. It answers the question: “Are you really this person?” The user uses an authentication method (authentication based on knowledge, physical biometric authentication or behavioral biometric authentication).

Figure 2. Dwell time and flight times of user

During this phase, we record and calculate the user biometric data f_i^d (Press key1-Release key1), f_i^{L1} (Release key1-Press key2), f_i^{L2} (Press key1 – Press key 2) and f_i^{L3} (Release key 1 – Release key 2). Those functions present the user's temporary profile that will be noted "fc" for claimed user.

Classification

Classification phase is the most important step, it answers the following question is the claimed user the original user or an impostor?

According to Banerjee and Woodard (2012), There are many classification methods can be used in keystroke dynamic field specially in classification phase. They categorized those methods into four categories: (1) statistical algorithms based on distance measurement like Euclidean distance and Manhattan distance. (2) Artificial neural network inspired by biological neurons working, adapted later to the field of statistics and then used on Behavioral Biometrics. the examples of this method are backpropagation, sum-of-products and hybrid sum-of-products. (3) Pattern Recognition which is the process of recognizing patterns by using machine learning algorithm such as the nearest neighbor algorithms and SVM (Support Vector Machine). (4) Search Heuristics algorithms such as Particle Swarm Optimization, Ant Colony optimization and Genetic Algorithms.

We chose pattern recognition by using K-NN and K-FN based on Manhattan distance. We have already explained the reason for choosing these two methods and why we opted for Manhattan distance instead of Euclidean distance (Jaha and Kartit (2017)).

To decide if the user will be allowed or rejected we have to:

1. Calculate de Manhattan distance, based on the equation (a), between f_i^d , f_i^{L1} , f_i^{L2} and f_i^{L3} of the temporary profile and each f_{ij}^d , f_{ij}^{L1} , f_{ij}^{L2} and f_{ji}^{L3} captured during enrollment phase according to the equation (b).

$$\sum_{i=1}^n |x_i - y_i| \quad (a)$$

$$D_i = \begin{cases} \sum_{j=1}^k |fg_{ij}^d - fc_i^d| \\ \sum_{j=1}^{k-1} |fg_{ij}^{\partial} - fc_i^{\partial}| \end{cases} \quad (b)$$

with: $\partial \in \{11, 12, 13\}$

$k=1, \dots, K$: number of pressed keys.

$i=1, \dots, n$: number of enrollment attempts.

2. We have to choose the 1-NN (One-Nearest Neighbor), the K factor in our case is equal to 1, by selecting the one minimum Manhattan distance $D_{\min}(c)$ from all D_i , with $i=1, \dots, n$, of all feature acquisitions stored in enrollment phase.

$$D_{\min} = \text{MIN}(D_i(f^{\partial})), \text{ with } \partial \in \{d, 11, 12, 13\} \quad (c)$$

3. We have also to calculate 1-FN (One-Furthest Neighbor) by determining the one maximum Manhattan distance $D_{\max}(d)$ from all D_i .

$$D_{\max} = \text{MAX}(D_i(f^{\partial})), \text{ with } \partial \in \{d, 11, 12, 13\} \quad (d)$$

4. Then we compare $D_{\max}$ and $D_{\min}$ with thresholds, so if the $D_{\max} \leq \text{MAX}_{\text{Threshold}}$ and $D_{\min} \leq \text{MIN}_{\text{Threshold}}$ the user will be accepted else the user will be rejected.

The reason to add F-NN to the classification phase is to better identify the genuine user and determine the lower and upper limits not to exceed.

Setting

We allowed the administrator to change some parameters to improve the result accuracy. These changes are made either to increase the security of access, or to allow a tired or sick user whose typing pattern is changing to access his system.

In the setting windows administrator can modify the following parameters:

1. The password length has an important effect to decrease the software's FAR and FRR. The longer the password is, the better we can capture the user features. Thus, longer phrase allowed obtaining much better accuracy.
2. According to Liakat, Monaco, Tappert and Qiu research threshold has to be variable. One of the conclusions this team reached is that using individual thresholds could improve the performance of the system. For our implementation, we calculated a threshold for each user using the same algorithm used in the authentication phase.

3. The next parameter is the number of entries used to generate the reference patterns, so a user's template is created. What we said for the password applies to number of enrollment attempts which has to be more than 10 times to capture a different states of mind of the user (comfortable, tired, etc.).
4. The last parameter is number of authentication, the user has not an infinite authentication attempts. The administrator can increase or decrease the authentication attempts to give more security for the system against impostor and another attempt for the genuine user to type his login and password correctly with the same rhythm as stored in the system database.

To validate and evaluate this biometric system, we used some error metrics adopted in most biometric systems to evaluate their accuracy. Therefore, we added a statistical section containing four graphs will present the following performance measures (see figure 3):

- FRR is the likelihood that the system will reject an authorized access attempts by the genuine user. FAR is the Percentage of attackers who are accidentally accepted. These two parameters are interlinked if the FAR goes down the FRR will go down and vice versa, the intersection value of these two graphs presents EER. Therefore, we have gathered these three parameters into a single graph in order to be able to determine the EER. The equations adopted to calculate each of these parameters are as follows:

$$FRR = \frac{FN}{FN + TP} \quad (e)$$

$$FAR = \frac{FP}{FP + TN} \quad (f)$$

Here, FP: False positive (imposter scores exceeding threshold), FN: False Negative (imposter scores exceeding threshold), TN: True Negative (imposter correctly rejected) and TP: True Positive (genuine correctly accepted)

- Sensitivity (Se) which is the proportion of true positives among total participants in the test. It is the ability of the software to correctly identify genuine. in statistics, Sensitivity is the true positive rate and in terms of equation, it's:

$$Se = \frac{TP}{TP + FN} \quad (g)$$

- Specificity (Sp) is the rate of impostors correctly detected (true negative). We calculated this value using the equation (h)

$$Sp = \frac{TN}{TN + FP} \quad (h)$$

- Accuracy (Acc) is the power and the ability of the software to distinguish the genuine users from imposters. We used (i) to determinate the software Accuracy value:

$$Acc = \frac{TP + TN}{TP + TN + FP + FN} \quad (i)$$

We intend to capture the biometric data of 100 participants (98 students and two teachers). The age of the participants varies between 18 and 33 with an average of 19.27. for the moment we are in the data collection phase to obtain at the end of the process a dataset that we will use to evaluate the current software based on K-NN.

FUTURE RESEARCH DIRECTIONS

Our next steps will be: (1) We will improve the software by optimizing the code for faster response time, and by adding some other useful features for the user and system administrator. (2) Since the quality of each biometric system is characterized by FAR, FRR EER, sensitivity, specificity and accuracy, we added a new statistic window dedicated to calculating those error metrics to examine performance and the quality of the software. For the time being, we have completed the programming phase and we are in the phase of data collection from the participants and creating the dataset. The result will be published in our next publication. (3) In order to conclude which method between K-NN using Manhattan distance and Euclidean distance gives the lower FAR, FRR and EER results, we will use the current code and replace K-NN with Euclidean distance then we will compare FAR, FRR and EER of the two methods.

Figure 3. Statistics window

CONCLUSION

5

This paper presented an Improving implementation of keystroke dynamics using KNN and Manhattan distance. We have discussed keystroke's biometric architecture and phases (registration, enrollment, authentication and classification) and showed the logic followed to transform the pseudo code, which we presented in a previous article (Jaha and Kartit (2017)), to operational software. We discussed also the mathematical equations used in the development of the software and we have specified the next step of our research that you can find in the future research directions section.

INTRODUCTION

Johanna Rutkowska first introduced the concept of the blue pill and the red pill (Rutkowska 2006). The blue pill is a hypervisor-based rootkit that takes control of a victim host computer. A red pill is a software tool designed to detect a blue pill.

A term that is closely related to trusted computing is the attestation concept (Zaidenberg et al. 2015), where a remote host or local software tries to ensure the integrity of the local machine. This concept was also researched by Kennell et al. (2003) in order to establish genuinity of a remote host. (a physical machine running the correct software as opposed to an emulator or a virtual machine or a physical machine running non-genuine software).

Since the introduction of blue pills, many red pills have been designed for their detection; however, more advanced blue pills have been designed to avoid detection.

Today, modern CPUs (such as Intel core iX processors or ARM8 architecture) feature hardware-supported virtualization. Hardware-supported virtualization provides new capabilities to virtual machine and emulators software. Thus, hardware-supported virtualization makes several “red pill” attempts futile. However, hardware-supported virtualization also provides new forensics opportunities and therefore, many new opportunities to create new red pills.

This chapter describes the red pill and blue pill situation on Intel and AMD virtualizations circa 2018 and the eighth generation of core iX CPUs.

BACKGROUND

Blue pill technology relies on hypervisor technology. This chapter reviews recent advances in x86 virtualization. These new instruction families enable blue pill and red pill technologies.

Hypervisors and Thin Hypervisors

A hypervisor is a type of computer software designed to run multiple operating systems on the same hardware.

As its name implies, a hypervisor has more permission than the operating system (i.e., the supervisor).

Just like the operating system supervises memory and hardware resources for the processes it runs, the hypervisor controls the hardware resources for each operating system.

Hypervisor research started with Popek et al. (1974) who classify hypervisors into two main categories:

1. Type I hypervisors, or boot hypervisors, are hypervisors that the machine starts from the hardware boot. The machine then starts the guest operating system. VMWare ESXi is an example of a modern Type I hypervisor.
2. Type II hypervisors, or hosted hypervisors, are hypervisors that start only after the operating system has started. A modern example for a Type II hypervisor is VMWare Desktop or Oracle Virtual Box.

Regular hypervisors are situated between the hardware and the supervisor (OS), catching interrupts and controlling memory addresses. The hypervisor decides which operating system owns each memory address and which operating system should handle each hardware interrupt.

There is a particular case of hypervisors that do not attempt to run multiple operating systems. Instead, these hypervisors, called “thin hypervisors”, supports running only one operating system on the target hardware. Thin hypervisors act as a microkernel that provides specific services. The thin hypervisor passes the handling of all (or almost all) hardware events and interrupts to a single operating system. It also includes very little memory management and relies on the guest OS memory management system and interrupt handling. Microsoft’s Deviceguard, TrulyProtect hypervisor for protection against reverse engineering (Averbuch et al. 2013) and Execution Whitelisting (Kiperberg et al. 2017) are examples of thin hypervisors. Virtually all blue pills are thin hypervisors.

x86 Virtualization

The x86 architecture, provide virtualization support by platform-specific instructions. Intel architecture and AMD architecture each provide three families of instructions for handling hypervisors. New processor generations optimize these instructions but their structure remains.

The x86 instructions are presented in Table 1.

Table 1. x86 virtualization instructions

	Intel Name	AMD Name	Usages
Virtual-ization instructions	VT-x	AMD-v	Starting a hypervisor
SLAT (second-level address translation)	EPT (Extended page tables)	RVI (Rapid virtualization indexing)	Multiple MMUs for multiple operating systems
IO MMU	VT-d	IOMMU	Assigning IO memory to specific operating systems
VM data structure	VMCS	VMCB	Holding VM information

Rootkits, Bootkits, and the Blue Pill

Once an attack is detected on any networked server, the recommended System Administrator action is to reinstall the server operating system. If the operating system is reinstalled (and fully patched with security patches), then the hacker may find herself locked outside of the system. It follows that the hacker has a desire to hide their tracks and maintain persistent access to the hacked servers. Therefore, hackers frequently install what is known as a “rootkit.”

A rootkit is a software that allows the hacker access to the victim computer resources. Furthermore, the rootkit hides itself and the processes the hacker runs to mask its existence. The rootkit goals are ease of access to victim computer resources and the best measures to hide its existence.

There are many ways to build rootkits from hijacking system calls and library functions and installing *setuid* programs to replacing innocent-looking binaries.

One of the ways a rootkit may operate is as a bootkit. A bootkit is a type of rootkit that boots (from the hard drive master boot record, UEFI, PXE, or other means) before the operating system starts. The bootkit starts its software before the OS starts and later boots the OS. The bootkit may patch the OS system calls to hide its processes and files.

The blue pill is a particular type of rootkit. Unlike normal rootkits and bootkits that modify the operating system in order to hide files and gain access to the system, the blue pill starts a hypervisor and, thus, gains more permissions than the operating system. The blue pill can run processes in the hypervisor address space that are not visible or swappable by the operating system scheduler.

The Original Blue Pill and Subverting Attacks

Rutkowska (2006) introduced the blue pill concept in 2006. The blue pill approach was an innovative rootkit approach that was relatively unresearched at the time. Since Rutkowska introduced the first blue pill, there have been several suggestions on how a blue pill can be detected (for example, the memory location of the IDT vector) and advances in x86 virtualization technology that make such detection more difficult.

Paranoid Fish And Other Red Pills

Paranoid fish (Pafish) (Ortega 2016) is currently the *de facto* standard red pill for blue pill detection. Pafish includes multiple tests capable of detecting most known blue pills when running under Linux or Windows. Many of the tests to detect a hypervisor assume it is not trying to hide by looking up specific values in memory.

Local timing methods are employed to try to flush out a blue pill. These tests perform the following steps:

1. Take the local time (for example, RDTSC instruction).
2. Execute an operation that must be intercepted by a hypervisor (for example, CPUID instruction).
3. retake the local time again to obtain elapsed time.

The underlying assumption is that step (2) takes significantly longer when a hypervisor is active. The elapsed time is compared against a threshold to determine if a hypervisor is active.

Blue Chicken

Rutkowska et al. (2007) introduced the blue chicken blue pill one year after the original blue pill. The blue chicken blue pill detects the red pill inspection attempts and unloads itself, and then restarts after the detection attempts are over. The blue chicken method is not recommended today because a hypervisor can be loaded after the blue pill unload itself. Then, if the blue pill tries to reload itself, the new hypervisor can detect it and prevent the blue pill from loading. The new hypervisor can even act as a blue pill, allowing the original blue pill to load and inspect its operational logic.

The Human Factor

Installing a hypervisor on any system has a performance penalty of several per cents. This performance loss occurs even if the hypervisor is not performing any activity. Using a hypervisor introduce a “second level address translation” i.e. when accessing any memory address another memory lookup occurs which has minor performance cost. This is the reason for the minor performance loss.

It is particularly true if a malicious blue pill is running and mining cryptocurrencies or spying on the user or performing other activities.

Humans are using most systems. Since humans have poor ability to measure and compare response times minor performance loss is usually not noticed. Even if the user is familiar with the system (such as a computer one uses daily), it is quite unlikely that they will notice that the system is running 10% slower. Furthermore, in some cases, the target system can be a server that is not commonly used. In these cases, even a performance drop of 30–50% may be undetected as slow responses are attributed to network latencies etc.

In extreme cases of a performance drop, the user may notice something is wrong even without other indications.

In other cases, a system with constant performance evaluation may be running (for example, calculating nodes per second on a graph problem); in such cases, a sudden drop in the system performance will be noticed.

For the red pill to be an efficient detector without too many false positive results, the performance drop must be significant. Minor drops in performance are usually undetectable. In small-scale tests, minor drops can be attributed to interrupts. In larger scale tests, these drops can be attributed to OS patches, other software, etc.

Modern computers are complex systems and regularly receive interrupts and events from multiple sources, software updates etc.; therefore, using small performance drops will result in multiple false positive detections.

REMOTE RED PILLS

“Remote red pills” refers to situations where a trusted third party is available to test the inspected system. These tests make more sense as they do not rely on a system that is considered untrustworthy.

If such a remote system is available, then these tests can attest the system with greater confidence than local tests. Unfortunately, for many real-world cases and scenarios, such reliable third-party systems do not exist.

Kennell's Timing Method and Derived Attacks

Kennell et al. (2003) proposed a method to perform a remote hypervisor red pill based on computation side effects. Such side effects include TLB and cache hits and misses as well as real-world time that the computation consumes.

According to Kennell's method, the attested computer receives a "challenge" (computation request) from a remote server.

The computation of the challenge causes several computational side effects such as TLB hits, TLB misses, cache hits, cache eviction, etc. The challenge contains several stages in which the side effects of the prior stage are added to the computation result and thereby affect the result of the next phase. In order to pass the Kennel test, the tested computer must not only produce the same results for the computation itself but also compute accurate results for the side effects as well. Furthermore, the computation must be completed in a short time (the time it would take a non-virtual machine to calculate). The Kennell test relies on the fact that if a blue pill or an emulator is running the side effects are bound to be different. Thus, the calculation of side effects must be done separately and consume more time. Thus the response to the challenge on an emulated machine or virtual machine is bound to be wrong or arrive too late. The Kennell test will declare that the machine is not genuine in both cases.

Kennell's method came under direct attack the following year. Shankar et al. (2004) claimed that performance side effects are not sufficient as a method for software detection.

Kennell (2004) has answered these claims, and the matter rested until virtualization became commonly available in modern PCs.

Kiperberg et al. (2013) claimed that the Kennell method could be replicated on modern PCs with hardware virtualization. This result was short-lived as Intel changed their caching algorithm the following year. Furthermore, Intel has not shared its caching algorithms.

However, Kennell tests rely on the availability of certain algorithms, such as CPU caching algorithms, which are not commonly available. These algorithms are considered trade secrets. Furthermore, Intel has changed the caching algorithms of their core iX platform between the second and third generations and changed them again to combat the "meltdown" (Lipp et al. 2018) and "spectre" (Kocher et al. 2018) weaknesses. Thus supporting the Kennell tests on modern hardware require reversing the architecture caching algorithm and is difficult and time-consuming. Supporting the Kennell tests on all recent Intel/AMD architectures can be a menial task that calls for further research.

Network-Based Attacks

Because Kennell has shown that several operations take a significantly longer time when a blue pill is running, it is possible to construct a network-based rootkit using other network servers instead of a Kennell-based attestation server.

For example, if a network-based NTP (network time) server is available and can be considered trustworthy, then it is possible to construct a "network-based blue pill."

The network-based red pill scheme is as follows:

1. Query a network time server.
2. Perform instructions that may take significantly longer if a blue pill is present (for example CPUID) * N times.
3. Query the network time server and obtain the difference.

4. Compare the time required to perform CPUID against a threshold.

The time measurements can be done more accurately by pinging other computers in the network as well as the default gateway.

TPM-BASED RED PILLS

The Trusted Platform Module (TPM) is a device that is found on most modern computers. TPM includes several performance counters that take measurements during the system boot.

The TPMs are developed using hardware obfuscation methods that prevent them from being reversed easily.

One of the main goals of the TPM is to attest the hardware and software that are currently running. This is performed using the following steps:

1. Establish a trust nexus.
2. Maintain a chain of trust.
3. Perform TPM attestation (remote and local).

Establishing a Trust Nexus

The TPM chip itself is the trust nexus. The TPM is built using hardware obfuscations, and its internals cannot be easily reversed. Tarnovsky (2010, 2012) has proved that specific TPM models can be attacked; however, there are no known attacks on modern TPM modules. If the risk that a modern TPM chip will be hacked is accepted (or considered negligible), then the TPM can serve as a root of trust (or trust nexus).

Chain of Trust

The TPM is capable of attesting the UEFI BIOS.

Using secureboot, the UEFI BIOS can ensure that the operating system or boot hypervisor boot loader is trusted.

The boot loader can attest the operating system.

The operating system can attest the software that runs on top it.

Thus, barring an unknown operating system bug or 0-day, the chain of trust can attest the software that runs on the end-point, providing that the trust nexus can be attested.

TPM Attestation

TPM supports local and remote attestation.

When a system with TPM boots, performance counters values are calculated and stored in the TPM performance counters. Both methods rely on the correct values to be stored on the TPM performance counter for the

When running a remote attestation, the remote computer sends the attested machine a challenge. The challenge must be encrypted using the correct encryption key, which can only be calculated if the correct values reside in the performance counter. If the correct values reside in the performance counters,

then the root of trust is set. The root of trust should attest the next chain in the chain of trust, and each link in the chain should attest the next link. If the correct values are not found, then it is impossible (at least without brute force attack or breaking the cypher) to provide the correct response to the challenge, and the attestation will fail.

In local attestation, the system is encrypted using a key that can only be obtained on a trusted system.

If the system is not trusted, then it is impossible to decrypt the system and pass the local attestation test.

LOCAL RED PILLS

Local red pills are tests performed by the tested machine and contained within the tested machine. These tests cannot be considered reliable as computation is performed on an untrustworthy machine (the very same machine is both inspecting and being inspected). However, in many real-life scenarios, there is no TPM chip available or similar third party chip or server that one can use for attestation.

If no third party root of trust is available, then one is left with running local code on an untrustworthy machine to provide attestation in a best effort attempt to detect blue pills on the inspected machine.

Paranoid Fish Tests

Paranoid Fish (Pafish) tests include the following:

1. Specific and paravirtualization tests – These tests are designed to detect specific commercial hypervisors (that do not try to hide)
2. Timing tests (Pafish includes two timing tests)
 - a. RDTSC, CPUID, RDTSC < 1000 cycles.
 - b. This test runs in userspace.
 - c. It runs the CPUID instruction, which must be intercepted by a hypervisor. As a result of the required context switch, the time required for the three instructions acts as a tell-tale sign for hypervisor presence (the red pill).
 - d. RDTSC, RDTSC < 750 cycles - This test involves calling two RDTSC instructions and measuring the response times. It is designed to ensure that the hypervisor is not intercepting the RDTSC instruction.
 - e. In both tests, an irregular high result will be obtained due to an intercept or context switch. To avoid false positives due to the irregular time required for the context switch, Pafish performs an average over ten runs.
3. Sandbox tests – These tests detect if the system is some sandbox. The tests measure if there is no user interaction or mouse movement.

Defeating Paranoid Fish Timing Tests

Most Pafish tests can be overcome using the following methods:

1. Instruction replacement – The CPUID operating can be detected and replaced by the hypervisor. In that method, the first time that CPUID is called a context switch will occur and, indeed, take a long time; however, further instructions can be replaced with another instruction that generates a similar response (such as generating an interrupt and returning with IRET).

2. Tampering with RDTSC - The hypervisor is allowed to intercept calls to RDTSC and similar calls and provide its own responses. The hypervisor may run its own code and return values that are smaller than the values obtained from the CPU. These values can take into consideration the time spent in the hypervisor. However, RDTSC time measurements are needed for the operating system to function correctly. Tampering with RDTSC return values may cause system instability.
3. Intel allows the time measurements (in CPU cycles) on the VM to be slower than on the actual machine; for example, every two CPU cycles on the physical PC can be considered as only one CPU cycle on the guest. This method can offset several of the red pill tests as operations no longer take “too much time.”
4. However, this test work with a constant multiplication factor. In real life, a constant multiplication factor does not occur. Some CPU opcodes require context switches and are much slower when a hypervisor is present while other operations take precisely the same amount of time regardless of hypervisor presence. Thus, These tests can be offset by performing operations that do not take longer on a VM (such as ADDing, ORing, and NOPing). It is possible to create a sequence of speedy operations that do not run slower on a VM (operations that do not require address translation, for example logical operations on registers, NOP etc.) . If the VM is running some clock adjustment were VM cycles are slower than real world cycles then these operations are likely to take too little time on the VM. (creating yet another type of red pill)

Augmenting Paranoid Fish

The Pafish timing test runs in user mode and examines only a limited set of instructions (for example, only RDTSC and not RDTSCP). By augmenting Pafish timing tests to run in kernel mode and trying multiple instructions (RDTSC, RDTSCP etc.), the Pafish tests can become more potent and harder to avoid.

Other well-known tests not found in Pafish include verifying the IDT pointer.

Nested Virtualization Tests

One of the tests not performed by Pafish is performing virtualization instructions (calling VMXON, VMREAD etc.) and performing complex virtualization operations such as EPT or IOMMU operations.

These instructions require a specific effort to support nested virtualization. Running these instructions efficiently poses extra complexity on the hypervisor, which is not implemented by some commercial hypervisors such as Oracle’s Virtual Box.

Calling these instructions introduces additional complexity, which the normal blue pill hypervisor may not meet or may not meet within time and complexity limits.

Like the CPUID instructions, all of Intel’s VMX instructions induce an exit from guest to host mode, making it mandatory to emulate and, thus, extending timing attacks to new instruction types and even mixing instructions from the family. Additionally, VMX instructions also modify the flags register in order to notify VMM software of success or failure of the instructions.

TYPES of VMX Instructions

The Intel architecture VMX instructions are presented (AMD instructions are similar). The understanding of these instructions is required in order to understand and overcome VMX instruction-based red pills.

VMXON instruction is used to switch the CPU into VMX mode. This instruction only affects CPU flags if it succeeds or fails.

VMXOFF instruction is used to turn off VMX mode in the CPU. This instruction only affects CPU flags if it succeeds or fails.

VMCLEAR instruction is used to initialize the VMCS control structure. It writes some data into the first 32 bits of the VMCS page while also affecting the CPU flags if it succeeds or fails. Moreover, it clears the running flag from the VMCS.

VMPTRLD instruction is used to load and mark a VMCS control structure as active or inactive. It affects some opaque data in the VMCS and also affects the CPU flags if it succeeds or fails.

VMWRITE instruction is used as an indirect way to write data into the VMCS data structure. It also affects CPU flags if it succeeds or fails.

VMREAD instruction is used as an indirect way to read data into the VMCS data structure. It also affects CPU flags if it succeeds or fails.

VMLAUNCH instruction is used to launch a VM. Other than the fact that it causes a guest VM to begin execution, it also affects CPU flags after the guest VM has finished its execution due to an exit from guest to host mode. This instruction will not allow a VMCS with a running flag to execute.

VMRESUME instruction works similarly to VMLAUNCH except it will only allow a VMCS, which is marked as running to execute. Additionally, this instruction also affects the CPU flags if it succeeds or fails.

INVEPT instruction causes the CPU to drop cached translations associated with some (or all) EPT pointers stored in the TLB. The instruction also affects the CPU flags if it succeeds or fails.

INVVPID instruction causes the CPU to drop cached translations associated with the VPID pointers stored in the TLB. The instruction also affects the CPU flags if it succeeds or fails.

Defeating VMX Instruction Timing Tests

Timing attacks may be defeated in two ways: either by replacing instructions or by using the capabilities of the VMM in order to lie to the guest about how much time has passed before and after instruction execution.

Defeating VMX Instruction Behavioural Tests

VMX instruction behavioural attacks test the correctness of instruction execution. By following the CPU manufacturer's developer manual, an attacker can see what the correct behaviour of instruction is and which cases cause the instruction to fail or succeed and test each of these cases. The blue pill software role would be to make sure that each of these cases behaves according to the developer manual. If the attacker observes a case that behaves differently, then it can safely assume some VMM software controls the machine. Another class of behavioural test red pill might try actually to execute a virtual machine on its own.

Any VMX instruction operates the same when it comes to success or failure, clearing the CF, ZF, and OF flags in the flags register in case of success or setting them in case of some error.

In some cases, it is required by the blue pill software to save some state between each VMX instruction. These instructions include all those instructions that modify the VMCS directly or indirectly. In the following paragraphs, it is explained how a blue pill software can handle each of these VMX instructions.

VMPTRLD instruction should store the physical address given as its parameter for future use. Storing this value allows the blue pill software to make sure VMREAD and VMWRITE instructions, which require a previously loaded VMCS, also allow the VMCLEAR instruction to behave correctly as VMCLEAR's parameter is an active VMCS. The VMCS stored during the emulation of this instruction will be denoted as L_{12} VMCS, meaning it was created by some hypervisor running at emulation level one and describe a VM that will run at level two while level zero denotes the blue pill hypervisor.

VMCLEAR instruction will clear the running flag of a given VMCS. Because the VMCS structure is opaque and unknown to the red pill software, one can save this flag onto the VMCS itself to mandate persistency without having to allocate any extra memory. Additionally, if the given VMCS is the same as the one saved previously by the VMPTRLD instruction, then this information will be cleared as well.

VMREAD and VMWRITE instruction emulation require the blue pill software to create its own mapping from some VMCS field to some offset within the VMCS, allowing it to store and recall data from the VMCS structure. The VMCS pointer used for storing and recalling data is the one stored previously during the emulation of the VMPTRLD instruction. Some of Intel's newer CPUs support a feature called VMCS shadowing, which allows guest software to directly interact with some VMCS without requiring an exit from guest to host, making VMREAD and VMWRITE emulation easier.

VMRESUME and VMLAUNCH instructions emulation requires the blue pill software to create a shadow VMCS. The shadow VMCS is denoted as L_{02} VMCS, meaning it was created by level zero and describes a VM running at level two. The host state of L_{02} VMCS will describe the blue pill hypervisor instead of the one described by the red pill running on the guest. When an exit occurs from guest to host, it will first be to the blue pill hypervisor, and then, maybe, the red pill hypervisor will be executed if necessary. Thus, the time required to go from a guest executing at level 2 to level 1 by indirectly having to go through level 0. Therefore, it is impossible for the guest running at level 2 to have a similar performance of that running at level 1. Consequently, any red pill that can successfully detect a guest by timing and performance tests can easily expose a nested blue pill hypervisor by simply observing performance.

Multicore Red Pills

When discussing Pafish timing attacks, it has been shown how some x86 instructions can be used to perform timing attacks, i.e., they take a much longer time to operate when a hypervisor or red pill is present.

In an attempt to defeat these detection methods, a blue pill can take certain operations such as tampering with CPU time (RDTSC) instructions. Tampering with CPU timing can be used to change the CPU time measurements and build efficient rootkits.

However, there are other methods a core can use to measure time and CPU cycles.

Most modern CPUs include more than one core. All Intel's core iX processors include 4–36 cores. The extra cores (all cores beyond the first) can be used for time measurements. By performing certain operations in CPU registers (such as ADDing, ORing, or NOPing) a specific amount of time can be considered wasted and efficient time measurement can be provided even if the time measurement instructions (RDTSC) have been manipulated.

Undocumented Opcodes-Based Attacks

The x86 opcodes vary in length from 1 to 19 bytes. This massive address space leaves vast room for opcodes.

Domas (2017) mapped the opcodes and compared them with the x86 specs. Domas found many ($\sim 10^5$) undocumented opcodes in the x86 architecture. It is speculated that Intel's engineers use these instructions for internal testing. While the behaviour of these opcodes is undefined, by definition, it is not unlikely that by calling one of these opcodes one could generate a different behaviour if a red pill hypervisor is running. Further research on this subject is required.

SOLUTIONS AND RECOMMENDATIONS

As demonstrated above, there are numerous ways in which a hypervisor can hide and avoid detection and numerous ways in which a hypervisor can be detected. It is recommended to take the following precautions as a malicious blue pill must be avoided at all costs:

1. Install a TPM on the system and attest the UEFI BIOS.
2. Start an attested trusted hypervisor that will prevent any subversion attacks.
3. Update the applications or homegrown code if new subverting attacks are discovered and published (0-days).

If a red pill is required and a primordial hypervisor cannot be installed, then the recommended red pill method is to use remote attestation methods whenever possible.

Local attestation by the local system should be avoided, especially if the malicious hypervisor's designers can review the local attestation code and design the hypervisor so that it passes the local test with high probability.

However, if local attestation is required, then it is recommended to use the multiple cores available in all modern CPUs for time-based attestation. Such methods should be used as a last resort, and remote attestation or network timing-based methods are preferred. A malicious blue pill hypervisor can block these methods; however, tampering with NMIs between cores will usually introduce noticeable latency to the system.

It is also possible that unknown opcodes can be researched to provide new red pills.

FUTURE RESEARCH DIRECTIONS

Further research based on undocumented opcodes (Domas 2017) as described above is recommended. There are many unknown opcodes, and it is very likely that some of those opcodes behave differently in the presence of a hypervisor. Such opcodes may also behave differently in nested and ordinary virtualization.

If such instructions are found, then it will be challenging to overcome these red pill detections. The blue pill hypervisor may attempt to interpret each page loaded into memory and detect such instructions; however, because each instruction in x86 takes a variable number of bytes, detecting the offending instructions may force time-consuming tests of each memory page that gains execution permissions and, thus, may be detectable by other means.

Researching how the Kennell method can apply to new CPUs, especially generation 9 Intel CPUs with the new algorithms after spectre and meltdown attacks, is also an exciting research topic.

CONCLUSION

It was shown how modern blue pills and red pills could be constructed.

For constructing modern blue pills, the detection code must be available and analyzed.

It is quite possible that a given red pill (if analyzed by the blue pill coders) can be detected and bypassed; however, it is not possible to code a blue pill that will bypass all possible tests and still maintain proper system performance.

KEY TERMS AND DEFINITIONS

Blue Pill: Blue pill is a type of software that runs as a malicious thin hypervisor-based rootkit.

Bootkit: A rootkit that boots when the computer boots, usually before the operating system starts. The bootkit installs itself on the hard drive master boot record (MBR) or BIOS and gains control of the system before the operating system ever has control.

Chain of Trust: Group of computer components that starts at a trust nexus. Through a series of operations, each component in the chain adds functionality and verifies the next component. The final component is trusted if all components in the chain complete successful verification and then the nexus can indeed be trusted.

Hypervisor: A hypervisor is a type of computer software designed to run multiple operating systems on the same hardware.

Privilege Ring: Intel architecture defines several privilege “rings” (protection rings) that refer to the current state of the system. These rings are ring 3 (user mode) where certain operations are not allowed, ring 0 (supervisor mode/operating system mode) where access to hardware devices is allowed, and hypervisor mode (ring –1) where hypervisor operations are allowed. Rings 1 and 2 also exist: these “in-between” privilege levels had historical usage but are mainly unused in modern systems.

Red Pill: Red pill is a type of software that is used to detect and defeat blue pills. The goal of the red pill is to provide an answer to the question, “Is the computer currently running a blue pill?” in the most reliable possible method.

Rootkit: Rootkit is malicious software that grants unauthorized user-persistent access to the victim computer resources. The rootkit is also designed to mask its existence such that the administrator will not be able to detect it.

Thin Hypervisor: A hypervisor that is designed to support only one operating system.

Trusted Platform Module (TPM): The Trusted Platform Module (ISO/IEC 11889) is an international standard and specification for a secure cryptoprocessor. The TPM is a dedicated microcontroller designed with hardware obfuscation to prevent tampering. The TPM provides cryptographic operations and can measure the CPU and running software for platform attestation.

Arm Hypervisor and Trustzone Alternatives

Nezer Jacob Zaidenberg

INTRODUCTION

ARM holdings have proposed TrustZone™ as means to create a Trusted Execution Environment (TEE) on the ARM platform. On many scenarios, such Trust Execution Environment is required to provide DRM support, secure wallets, Trusted endpoints, point of sale and other embedded systems.

Other than the mobile platform, TrustZone™ can be found in other ARM socs, such as AMD with their “Hiero falcon”, AppleMicros X-Gene3, Cavium Thunder X etcetera.

Virtualization as a security solution is also widespread. Safe execution through sandboxing is a standard method for security. Several applications offer methods for trapping sensitive instructions into a hypervisor. Cloud computing technology, initially designed for dynamic provisioning of computing resources, is by its nature exposed to the public. Therefore, the virtual machine is exposed to many threats. Also, as the ARM architecture-based servers technology spreads, ARM virtualization technology can ease filtering out threats and monitor activities.

Multiple vendors offer their own TEE implementations. Some TEE implementations such as Trustonic and Qualcomm QSEE are closed source while others are open source or provide source code for a fee. This chapter surveys Trusted computing alternatives for implementations. The chapter mainly considers alternatives with available source code that offers a complete solution for the TrustZone™ environment, and also offers some ARM virtualization alternatives.

BACKGROUND

Trusted Execution Environment

The ARM architecture allows for co-existence of a Trusted Execution Environment (TEE) and Rich Execution Environment (REE). Trusted Execution Environment is a secure area inside the central processor unit (hereby CPU). The Trusted Execution Environment runs its own operating system. The TEE operating system is a separate operating system that is running in parallel with the REE(main) operating system, in an isolated environment. The Trusted Execution Environment guarantees that the code and data loaded in the TEE are protected concerning confidentiality and integrity.

DOI: 10.4018/978-1-5225-9715-5.ch079

Rich Execution Environment is another area inside the CPU. The Rich Execution Environment runs a separate operating system. Usually, Google's Android or Apple's iOS. The Rich Execution Environment refers to the standard operating system that the device is running. The Rich Execution Environment offers significantly more features and applications and as a result, is vulnerable to attacks. In most cases, the Rich Execution Environment is the environment where most applications are running. The Rich Execution Environment receive services such as decryption keys from the Trusted Execution Environment.

The Trusted Execution Environment usually act as a monitor for the Rich Execution Environment.

The Trusted Execution Environment has higher permissions and usually have access to read the Rich Execution Environment memory and data structures. The Rich Execution Environment should not have access to the trusted Execution environment memory and data structures. The two worlds, the secured and the normal (not trusted, non-secured) worlds, can switch through the strict supervision of a Secure Monitor running in monitor mode. Switching between the secure and normal world can be done through a special instruction called "secure monitor call" or SMC. Software use SMC to communicate between the secure and normal worlds shared memory is used. TrustZone™ splits the SOC devices to the secure and normal worlds. TrustZone™ control the device hardware interrupts. TrustZone™ can route an interrupt to the secure world or the normal world. Like in the memory case, I/O and interrupts routing may change dynamically. TrustZone™ uses its own MMU. Operating systems and processes that execute in TrustZone™ do not share the same address space with their normal world counterparts. Thus, there is no need to have distinct TrustZone™ for each processor. A single TrustZone™ OS across multiple ARM processors/cores can manage all the device Trusted computing needs. The cryptographic keys are accessible only in TrustZone™. The manufacturer can burn platform-specific keys using fuses. These platform-specific keys are device specific, thus enabling protection in the end unit level.

Booting a Trusted Execution Environment must form a chain of trust in which a trust nexus verifies the next component on the boot chain. Each component verifies the next component until the system. Many vendors proposed.

ARM Permission Model

ARMv8 architecture has a unique approach to privilege levels.

The ARM platform has 4 exception (permission) levels.

ARM also has the secure world (TrustZone™) and the normal world (non-TrustZone™)

ARM Exception levels are described in Table 1 Each of the exception levels provides its own set of registers and can access the registers of the lower exception levels but not registers of higher exception levels. The general-purpose registers are shared.

Thus, moving to a different exception level on the ARM architecture does not require the expensive context switch that is associated with the x86 architecture.

ARMv7 architecture is similar to ARMv8. ARMv7 offers virtualization as an extension that is only available to some late ARMv7 models. ARMv7 does offer TrustZone™. Furthermore, ARMv7 is 32bit architecture while ARMv8 is 64bit (and 32bit) architecture.

Virtualization vs TrustZone™ Mode

The first question we must address is how the operating system should be verified. The REE operating system can be verified using HYP mode or TrustZone™. ARM has designed the TrustZone™ mode specifically for attesting and monitoring the Rich operating system. Only the vendor can install soft-

Table 1. Arm exception levels

Exception level	Meaning	Notes
Exception Level 0 (EL0)	Refers to the userspace code.	EL0 exists in both the secure and the normal world. EL0 is analogous to x86 “ring 3”.
Exception Level 1 (EL1)	Refers to the operating system code.	EL1 exists in both the secure and the normal world. EL1 is analogous to x86 “ring 0”.
Exception Level 2 (EL2)	Refers to the HYP mode.	EL2 exists only in the normal world EL2 is analogous to x86 “ring -1”.
Exception Level 3 (EL3)	TrustZone™	Refers to TrustZone™ as a special security mode that can monitor the ARM processor and may run a real-time security OS. There is no direct analogous mode, but related concepts in x86 are Intel’s ME or SMM.

ware on the TrustZone™ mode. In some cases, even the vendor receives the CPU from a 3rd party and has limited access. In those cases, even the vendor cannot install any software in TrustZone™ mode. However, if not deliberately prohibited by the manufacturer, everybody can install any software in HYP mode. This usually makes hypervisor code easier to install. This chapter examines the problem from the vendor standpoint. Therefore it is assumed that TrustZone™ is available.

The two main drawbacks of using virtualization are that virtualization mode is no longer available for other software that may want to run there. Also, TrustZone™ is monitored on boot by the BSP (Board Support Package); it cannot be modified or replaced as easy as the hypervisor boot loader or driver.

Resh et al. (2017) and Seshadri et al. (2007) provide examples of using hypervisor for endpoint security.

We examine several hypervisor implementations for completion. However, it is assumed that a TrustZone™ solution is preferable whenever TrustZone™ is available.

Virtualization Classification

Virtualization is the process of running multiple Operating systems on a single hardware or running microkernel to manage a single operating system. A hypervisor is a software component that provides virtualization. There are two types of hypervisors:

1. Full virtualization - The guests’ operating systems are running as it would on regular hardware.

It is not modified in any way or aware of the fact that it does not run on bare-metal hardware.

2. Para-virtualization – The guest operating system is aware that it runs as a guest. The guest’s operating system code is modified. The guest operating system does not attempt to communicate directly with the hardware. Instead, the guest operating systems uses hypercalls to communicate with the host hypervisor. Hypercall is a call from the guest to the host. Similar to system call from a user process to the operating system. When the guest’s operating system needs the host, for example, for I/O access and sometimes in critical sections. The hypercall trap to the hypervisor to perform a service on behalf of the guest. As multiple guests are trying to access the same hardware, the hypervisor needs to trap and synchronize these access. Using para-virtualization and hypercalls usually yields better performance then trapping.

In the taxonomy of the virtualization environment, virtualization environments have two design categorize

1. Complete monolithic - A single software responsible for providing access to the hardware to the guests. For example, VMware ESXi server.
2. Partially monolithic - The technology is an extension to the general-purpose operating system, such as KVM in Linux and VMWare Desktop or Microsoft Hyper-V
3. MicroKernel These are lightweight microkernels that a minimal set of services to the guests, mainly CPU virtualization and hardware access. Jailhouse and seL4 are examples for such microvisors (micro hypervisors).

Last virtualization pioneers Popek and Goldberg (1974) classified hypervisors to type I and type II
Type I hypervisors (or boot hypervisors) – are hypervisors that start at boot and start various guest operating systems. Examples include VMWare ESXi, Xen and IBM S/390 VM.

Type II Hypervisors (or hosted hypervisors) – are hypervisors that starts under a host operating system that already booted and took control of the machine. Examples include VMWare desktop.

For security and trusted computing purposes, mainly Type I hypervisors are of interest. Type II hypervisors can be disabled by the host OS (for example malicious software can cancel the hypervisor start sequence after reboot) and thus type 2 hypervisors serve minimal security purpose.

GlobalPlatform

GlobalPlatform is a nonprofit organization that consists of an alliance of many mobile device manufacturers. GlobalPlatform creates and publishes the standard for secure digital services for mobile devices. GlobalPlatform (2011) is the current standard for TEE platform under ARM.

GENERAL DYNAMICS OKL4

OKL4 is a microkernel that was originally developed, maintained and distributed by Open Kernel Labs.

The OKL4 operating system was based on the L4 operating system by Liedtke (1996).

The L4 microkernels family in its earlier form was called L3. L3 was a microkernel that was developed Liedtke in the 1980s on an i386 system and was deployed in a few thousands' installations, mainly education institutes. L3 suffered from a high overhead of IPC communication, which was over 100us. Liedtke, trying to reduce the IPC overhead problem, had re-implemented L3 completely and reduced the IPC overhead significantly to 5us, on i486. This new design was referred to as L4.

L4 had evolved over the years and become a family of L4 microkernels, to name a few, L4-embedded, Codezero, NICTA, seL4 etcetera. NICTA was maintained by OpenLabs which renamed it to OKL4 microkernel and stopped the open source development.

OKL4 (Heiser et al. 2010) is deeply covered in peer-reviewed publications. The OKL4 micro-visor supports both para-virtualization and pure virtualization. It is designed for the IoT industry, and supports, ARMv5, ARMv6, ARMv7ve and ARM8va. OKL4 is focused on embedded devices. OKL4 was originally open source software.

On 2012 general dynamics acquired the Open Kernel Labs. After the acquisition, General Dynamics changed OKL4 source code policy from open to closed source project. The latest available open source

OKL4 is from May 2013 and is still available to download from archive.org (and other sources). OKL4 has a sister open source project (supported by GeneralDynamics) called seL4, which is described later.

Installing OKL4 and running it is a challenging task that requires expertise. Open source OKL4 code must also be adapted to modern hardware.

Today OKL4 is still under development and support of General Dynamics.

One can also obtain the current OKL4 source code under a suitable license and NDAs.

This chapter refers to the latest available open source OKL4 from 2013 and not to current releases, and thus this chapter is not up to date with current releases (compared to other Trusted Execution Environment alternatives) but does not violate any NDAs

GOOGLE TRUSTY TEE

Trusty is a secure Operating System (OS) that was developed by Google.

Trusty provides a Trusted Execution Environment (TEE) for The Android (only) Operating system.

The Trusty OS doesn't require security specific hardware. Instead, Trusty TEE runs on the same processor as the normal Android OS. However, despite running on the same CPU, Trusty is isolated from the rest of the system. This is done using ARM TrustZone™ features that enable separate MMU for trusty (in TrustZone™) and the normal world OS. TrustZone™ allows Trusty to create an isolated secure execution environment and provide certain services to the REE OS (i.e. Android).

Trusty consists of:

- A small operating system kernel. The Trusty kernel is derived from Little Kernel. Little Kernel is a small operating system that is also used as Android boot loader.
- A Linux kernel driver that acts as a mediator between the TEE (Trusty) and REE (Android) environments.
- An Android userspace library that provides a way to communicate between the REE (Android) and TEE (Trusty) applications using the kernel driver.

Trusty is compatible with ARM and Intel processors. On ARM systems, Trusty uses ARM's Trust-zone™ to virtualize the CPU and create a secure, trusted execution environment. Similar support is also available on Intel x86 platforms using Intel's Virtualization Technology.

LINARO OP-TEE

Linaro security working group and STMicroelectronics have teamed to create OP-TEE.

OP-TEE follows GlobalPlatform specification (2011) and implements version 1.1 of GlobalPlatform TEE client API and TEE internal API.

OP-TEE is an open source project and is widely available under BSD 2-clause license and (Kernel parts) GPLv2 license. OP-TEE has a small footprint and minimal effect on the running system. OP-TEE has vast community support.

Like Trusty above, OP-TEE consists of 3 main components.

- A lightweight, secure operating system. The OP-TEE operating system consists of several modules, such as memory management, interrupt handling, scheduler. Also, OP-TEE implements a hardware abstraction layer as it supports various processors and hardware. The OPTEE operating system also provides a capability to run user-space applications (typically referred to as Trustlets) in the secure world. These applications are provided with the GlobalPlatform TEE Internal API which allows them to ask for internal, secure-only, OS services
- A non-secure user-space client that is composed of two components: (1) a user-space/kernel-space mediator and (2) libraries that implement the GlobalPlatform TEE Client API.
- A kernel driver that performs the transitions between the secure and normal worlds

SOLUTIONS AND RECOMMENDATIONS

The features of the various TEE alternatives are shown in Table 2.

Table 2. Summarizes the TrustZone™ alternatives on ARM circa 2018

	OKL4	OP TEE	Trusty TEE
Vendor	General Dynamics since 2012, Originally Open Kernel Labs. (2006-2012)	Linaro	Google
Background	OKL4 Hypervisor designed by General Dynamics Mission Systems delivers a real-time embedded Type 1 virtualization solution using our proprietary OKL4 technology. Combined with Lightweight Execution Environments (LWEE) and proven commercial Linux, VxWorks or Android distributions, the OKL4 Hypervisor enables the ability to produce fully integrated, secure, and performance-optimized solutions with guaranteed separation. Applications, functions and processes running on separate dedicated operating systems and hardware can now be consolidated into one intelligent system, allowing for highly scalable and secure systems at a lower cost. ¹	OP-TEE is an Open Source TEE and is the result of collaboration work between STMicroelectronics and Linaro Security Working Group. It contains the complete stack from normal world client API's (optee_client), the Linux kernel TEE driver (optee_linuxdriver), the Trusted OS + the secure monitor (optee_os) and the test suite (xtest). ²	Trusty is a secure Operating System (OS) that provides a Trusted Execution Environment (TEE) for Android. The Trusty OS runs on the same processor as the Android OS, but Trusty is isolated from the rest of the system by both hardware and software. Trusty and Android run parallel to each other. Trusty has access to the full power of a device's CPU and memory but is completely isolated. Trusty's isolation protects it from malicious apps installed by the user and potential vulnerabilities that may be discovered in Android. ³
Source model	Open source until 2013. Currently closed source. Links to the older code base are still available. Current sources may be purchased from GD with some licenses and NDA restrictions. Hardware support	ARM8, ARM7, ARM6	ARMv7, ARMv8	ARMv8, ARMv7 and Intel (Using Intel VT-x)
Secure to normal world interface. Ease of Development on normal world	Proprietary API	ioctl	IOCTL / using port
Logging support	Multiple mechanisms exist	Configurable Log level (such as in Linux). Several macros DMSG/EMSG/IMSG/ FMSG may be used and redirected to UART	standard output. Data written to standard output can be routed (depending on the LK debug level) to UART or a memory log available on the non-secure side, depending on the platform and configuration. Non-critical debug logs and messages should go in standard output. The read() and ioctl() methods are no-ops and should return an ERR_NOT_SUPPORTED error.
Power up delay	Not noticeable	Not noticeable	Not noticeable

OTHER ALTERNATIVES

These alternatives are not as strong as the alternatives mentioned above

Jailhouse

Announced by Siemens at November 2013, Jailhouse (Baryshnikov 2016) is a type 2 partitioning microvisor for Linux hosts. A partitioning microvisor is a microvisor that controls access to resources and isolates them from the general-purpose operating system - GPOS or other guests. Partitioning means a strict allocation of the system resources. The hosting Linux is referred to as the “Root cell”, and the guests are “inmates”. Jailhouse is not an operating system; it a resource access controller. Jailhouse is controlled from the Linux host, which makes it reveals to hosting Linux, but not the guest.

Jailhouse is a bare-metal hypervisor, and in most cases, it is pure virtualization hypervisor, and as such can run many types of operating systems, such as FreeRTOS, Erika3, Linux and Zephyr. It supports ARMv8, ARMv7a, and x86_64. Jailhouse requires the machine to have at least two processors. One processor is used to run the hosting Linux, and the other processors may be assigned to Jailhouse. It requires the Linux kernel to reserve a contiguous memory at boot time. It requires a memory footprint of a few tens of megabytes, usually 50 megabytes.

The configuration of Jailhouse is done through a tool provided by Jailhouse. This tool scan sysfs and procfs, and then generates a device tree that describes the hardware as seen by the Linux host. This device tree is referred to as the cell configuration file. It is up to the user to edit the cell file to create a correct guest configuration. It is a process of trial and error.

Jailhouse targets the automation, robotics and IoT industries.

QSEE

QSEE is Qualcomm Secure Execution Environment. In the past, it was based on OKL4 until GeneralDynamics and Qualcomm failed to reach an agreement regarding licensing. Since 2015-6 Qualcomm has developed QSEE from scratch with no (direct) connection to GeneralDynamics.

QSEE is closed source (and Qualcomm does not provide source code licenses) Therefore, QSEE fails this chapter precondition of source availability and is not part of this survey.

Prior releases of QSEE suffered from several well-documented security problems.

seL4

seL4 like OKL4 is also based on the L4 microkernel. seL4 (Klein et al. 2009) is a microvisor that was implemented by Open Kernels labs (and later GeneralDynamics). seL4 is not as popular as OKL4. One of the powerful features of seL4 is the fact that it has been formally verified to be correct.

seL4 compared to OKL4, is an open source kernel. seL4 is the sole kernel that is mathematically proven secure and safe. L4-embedded, or NICTA embedded, was adopted by Qualcomm as a real-time operating system for their wireless modem processors firmware.

The basic rules of the L4 kernel design are minimalism. Leidtke (1996) formulated the rule of minimization as follows:

“A concept is tolerated inside the u-microkernel only if moving it outside the kernel, i.e. permitting competing implementation would prevent the implementation of system required functionality”.

This principle, also known as the no-policy in the kernel, is the core of the L4 microkernels design. Though operating systems tend to grow in size over the years, L4 footprint is considerably low. The seL4 footprint is 9600 lines of code. As a side effect of the minimization and performance, L4 microkernels do not strive to hardware abstraction. Half of the seL4 microkernel is agnostic to the underlying hardware.

L4 also demonstrates a new resource management scheme where all memory allocations are userspace driven. Another interesting feature of the L4 microkernels is the fact that interrupts are disabled while executing in kernel mode. This approach simplifies the implementation, increases the performance and eases the kernel verification. Direct process switch, which in general means that seL4 tries to avoid using the scheduler, is another exciting facet of L4. When a thread reaches a preemption point, the kernel switches to the first runnable thread, which in turn, executes on the time slice of the preempted thread.

seL4 runs on ARM, supports SMP and Uniprocessor. seL4 also provides real-time support.

TrustTonic

TrustTonic is a company known for its TrustZone technology in the mobile world, mainly Android. The TrustTonic operating system, Kinibi, is a closed source operating system. The Kinibi OS is widespread in the Android cellphone world. Kinibi provides data encryption and device authentication features. Kinibi also gives safe access to peripherals, such as the touch screen, NFC and fingerprint, through its TEE API, so that no malware in the REE can access secure communication and data. In addition, Kinibi can isolate sensitive code execution and secure data.

The secure boot chain of trust verifies kinibi, i.e. it is verified by the bootloader each time the device boots.

Above all that, Kinibi TEE applications has access to the network. This way, a trusted application can access remote services securely.

TrustTonic can also be found in the automotive industry. In this area, TrustTonic approaches data leakage, application overlapping and application re-packaging attacks. Application overlapping attack is an interception technique for stealing sensitive I/O, such as when a user enters its password. A repacking of an application is a method of modifying a program to steal sensitive data. For example, adding a log entry that prints sensitive information.

Trustonic offers an SDK, compliant with GlobalPlatform API standards, to help build Trusted Applications.

Xen

Announced at 2003 and developed initially at the University of Cambridge, by Ian Pratt, Xen is a hypervisor. Xen provides CPU virtualization Virtual interrupts, virtual MMU and inter-guest communication. In Xen, a virtual machine is referred to as Domain. Domain0, also known as Dom0, is the first domain that must run before any other virtual machine and it is usually Linux or BSD, and DomU is a virtual machine on top of the other domains. Domain0 requires access to the entire machine's hardware. Domain0 responsibility is managed through the Linux kernel. Xen's event channel provides communication between Dom0 and DomU. Whenever DomU issues a virtualized event, it uses this event channel. The event channel is used for para-virtualized guests. For a full virtualized guest, Xen uses QEMU. Xen's tool stack is the management tool to control guests. The fact that Xen uses Linux as Dom0 provides Xen with an abundant of hardware support and Linux software. Xen boots from the bootloader and is then loads the para-virtualized host.

This comes with some cost of performance. Virtualized I/O accesses and virtualized interrupts are routed from DomU Xen guests are delegated to Dom0. In addition, if a host interrupt occurs while DomU runs, then this interrupt would be served only when Dom0 is getting the processor. Thus, interrupts and events have an overhead.

Xen is available in ARM and x86, runs on SMP and UP. Xen is licensed GPL.

Xvisor

Announced at Apr 2012, Xvisor (Patal et al. 2015), is a monolithic, type 1 hypervisor independent of Linux. A monolithic hypervisor controls the hardware peripherals. Xvisor provides a minimal operating system, and it is not a microkernel. Xvisor can emulate devices and provides a path-through access to real devices. As an operating system, it has a memory management, scheduler, load balancer and threads. There are no processes in Xvisor. Furthermore, Xvisor is not POSIX compliant. Xvisor support SMP, so that a guest can use two or more processors. There are no restrictions on the number of processors, and Xvisor can execute on a single processor.

Xvisor provides an IPC between two guests through the use of an aliased guest region, which is a GPA (guest physical address) shared between two guests. In the Xvisor taxonomy, a processor can be Normal VCPU or an Orphan VCPU.

Normal VCPUs serve guests OSes, and Orphan VCPUs belongs to the hypervisor. Xvisor support ARM 32bit and 64bit and x86. Its footprint is less than 10MB, however, since it is a type 1 hypervisor, it is required to change the boot loader. Xvisor targets the infotainment market in the automobile world and automation in general. It is licensed GPL.

FUTURE RESEARCH DIRECTIONS

Research on ARM TEE is ongoing and proceeds in several fronts.

First and foremost, the current implementation and chain of trust are examined. Multiple errors and bugs are found and reported, and ongoing research is carried over to locate bugs in current versions of ARM TEEs. This research is carried over by ethical hackers trying to perfect the current TEE platforms and also by attackers who try to exploit weaknesses and elevate permissions on current ARM TEEs.

A new research direction is trying to globalize TEE API for ARM, Intel, AMD and other architecture. Creating cross platform TEE environment can provide benefits to application authors.

Such extensions can be completed by using platform-specific APIs such as Intel's SGX (Secure Guard Extensions) to provide platform independent code.

Last TrustZone™ and other extensions can be used for other means such as real-time processing (Ben Yehuda et al. 2018) and Control flow analysis (Abera et al. 2016). Using the TrustZone™ architecture for other purposes is another interesting research area.

CONCLUSION

This chapter surveyed the popular TEE alternatives available today. Each alternative has its own benefits. SoC vendors and Platform manufacturers can choose the desired implementation based on their requirements and preferences.

We found that for many applications the free, open source, community driven OP-TEE offers equivalent or even better features even when compared to commercial alternatives or alternatives backed by massive companies.

KEY TERMS AND DEFINITIONS

ARM Architecture: ARM (previously advanced RISC machine, Acron RISC machine) is a 32 or 64 bit RISC CPU architecture that is by far the most common architecture in use today in mobile devices and IoT. ARM architecture includes TrustZone™ since the 7th generation of the ARM architecture.

ARM Virtualization: ARM offered virtualization extensions to ARM7 architecture and virtualization instructions as part of ARM8 architecture.

Board Support Package (BSP): A minimal set of drivers and boot loader to boot the operating system.

Chain of Trust: Group of computer components that starts at a trust nexus. Through a series of operations, each component in the chain adds functionality and verifies the next component. The final component is trusted if all components in the chain complete successful verification and then the nexus can indeed be trusted.

GlobalPlatform: Is an organization that publishes the standard for secure mobile and embedded platform

Hypercall: The term is analogous to System call. A call by a user process or the operating system for the hypervisor to perform some service required by the operating system of process.

Hypervisor: The hypervisor is the software component that is responsible for running multiple operating systems on the same hardware.

L4: A family of microkernel operating systems by Liedtke initially. OKL4 and seL4 are operating systems that were derived from L4.

Normal World (Insecure World): The normal operating system that the given platform is running for normal applications. In most cases, this refers to Google's Android or Apple's iOS.

Rich Execution Environment (REE): Rich Execution Environment is another area inside the main processor. The Rich Execution Environment runs a separate operating system. Usually, Google's Android or Apple's iOS. The Rich Execution Environment refers to the standard operating system that the device is running. The Rich Execution Environment offers significantly more features and applications and as a result, is vulnerable to attacks.

Secure World: Secure world is the name for the secure, trusted execution environment (TEE) on ARM Architecture. It is running concurrently, on the same CPU as the normal world. However, ARM provides hardware and software mechanisms to ensure that the normal world and secure worlds are running on separate environments.

Trusted Execution Environment (TEE): A Trusted Execution Environment (TEE) is a secure area inside the main processor. The trusted execution environment runs a separate operating system in parallel to the main operating system in an isolated environment. The trusted execution environment guarantees the confidentiality and integrity of the code and data loaded in the TEE.

TrustZone™: An ARM Exception level that allows running TEE in a secure environment in parallel to the normal ARM environment.

Glossary

Academic Cheating: An individual who does not utilize their own intelligence to give their interpretation of the content.

Activism: A strategy implementing a form of forceful demonstration in order to bring about partisan or societal transformation.

Addiction or Addictive Behaviour: Actions which a person can no longer control. Someone may go online to send an e-mail, get distracted and remain online for several hours, and possibly forget to send the e-mail.

Alternative Media Outlets: In Singapore, this refers to platforms which are not under the ownership of Singapore's mainstream media organisations: Mediacorp and Singapore Press Holdings. These sites predominantly accept posts from contributors who may be anonymous.

AMNSTE: An acronym for a research tool developed by the authors during the on-going research project, Affiliate Marketing Network Simulation and Testing Environment, which has been previously published.

Anonymity: Anonymity and thus anonymous data is any information from which the person to whom the data relates cannot be identified, whether by the company processing the data or by any other person.

Anonymization: A process of destroying on-line tracks of the data that could be used to link it to its originator.

Anxiety: A mental health disorder which includes symptoms of worry, anxiety, and/or fear that are intense enough to disrupt one's daily activities.

API: Application programming interface, a set of subroutine definitions, communication protocols, and tools for building software.

Approach: LCT step used more by contact-driven offenders to facilitate in-person meeting.

ARM Architecture: ARM (previously advanced RISC machine, Acron RISC machine) is a 32 or 64 bit RISC CPU architecture that is by far the most common architecture in use today in mobile devices and IoT. ARM architecture includes TrustZone™ since the 7th generation of the ARM architecture.

ARM Virtualization: ARM offered virtualization extensions to ARM7 architecture and virtualization instructions as part of ARM8 architecture.

Article Scraping: It is a process of scraping of the articles from the blogs or websites.

Artificial Intelligence (AI): A multidisciplinary field of research and engineering which studies the human functions that can be emulated by different types of machines.

Audit and Policy Mechanisms: Is a section of avatar-based management techniques.

Auditing: The process of conducting an official inspection of a company or its accounts.

Authentication: Permission to access something, which is confidential. The authentication is only provided to authentic users.

Avatar-Based Management: Is control methods and techniques introduced by V. Mkrttchian in 2018.

Axial Coding: The process of identifying the relationships between the categories and linking them together. The process yields subcategories that are grouped under a specific category. This process takes place after open coding.

Big Data: A data set this is too large for “standard” software programs, and is generally used to identify large trends, and predict behaviors and outcomes.

Bitcoin: A digital cryptocurrency that is used for transactions in many black markets of the dark web. Invented in 2008 by Satoshi Nakamoto to create a decentralized digital currency used to record peer-to-peer transactions generated by complicated mathematical models to ensure security without the need for intermediaries such as central banks.

Block Chain: A list of records, called blocks, which are linked using cryptography and used as a ledger mechanism in cryptocurrency. Each block contains a cryptographic hash of the previous block a timestamp, and transaction data.

Blue Pill: Blue pill is a type of software that runs as a malicious thin hypervisor-based rootkit.

Board Support Package (BSP): A minimal set of drivers and boot loader to boot the operating system.

Boot Loader: A small piece of code that provides minimal functions. The boot loader is executed prior to booting the operating system. The boot loader typically provides minimal hardware drivers, file system support etc. that are required for reading the operating system code.

Bootkit: A rootkit that boots when the computer boots, usually before the operating system starts. The bootkit installs itself on the hard drive master boot record (MBR) or BIOS and gains control of the system before the operating system ever has control.

Bot: It is a virtual robot created to automotive task both simple and repetitive.

Botmaster: Botmaster is the master of bots on the network. A botmaster is responsible for keeping the bot online, sending control commands to bots for its operation, making sure to fix issues with bots, and set a set of rules for bots to function.

Botnet: A botnet is a collection of bots. Botnets originate many types of attacks like distributed denial-of-service attack (DDoS attack), data theft, spamming, and intrusion to systems and networks.

Bots: Any system connected to Internet becomes a bot when it runs automated tasks or scripts over the internet. Majority of the malicious web traffic gets originated from bots.

Brightfield: All criminal cases in a particular area known to the authorities.

Bullying: Arrogant attitude of people who oppress their peers through acts of physical and verbal violence. It is diffused mostly in scholar and juvenile contexts.

C&C Server: A command and control server (C&C server) is a system that issues directives to other connected systems that have been infected with rootkits or other types of malware, such as ransomware.

CAPTCHA: Completely automated public Turing test to state computers and humans separately is a technique implemented in some banking systems whose aim is to render bots by creating and rating tests that humans can clear but existing computer programs cannot.

Cashless Policy: A policy that discourages the use of huge raw cash for transactions but encourages the use of bank transfer, ATM card, POS, and other financial instruments for transferring cash in transactions.

Catfishing: Using digital tools and techniques to post false information, profiles, and or photographs with the sole purpose of intentionally manipulating, misleading, or harming others.

Certificate Transparency: Google's certificate transparency project repairs several structural defects in the SSL certificate system, which is the key cryptographic system that triggers all HTTPS connections.

Chain of Trust: Group of computer components that starts at a trust nexus. Through a series of operations, each component in the chain adds functionality and verifies the next component. The final component is trusted if all components in the chain complete successful verification and then the nexus can indeed be trusted.

Child Pornography: Any visual depiction of sexually explicit conduct involving a minor.

Child Prostitution: A youth involved in sexual activity for profit, whether financial or otherwise.

Child Sex Tourism: The commercial sexual exploitation of children by people who travel from one location to another and take part in sexual acts with children.

Child Sex Trafficking: The recruitment, harboring, transportation, provision, obtaining, patronizing, or soliciting of a minor for the purpose of a commercial sex act.

Cleynet: Mainstream websites that are indexed by popular search engines, like Yandex, Google, and Bing.

Click Spam: It is a process of executing clicks on behalf of user without the knowledge of user.

Clickbait: Web article with an attention-gathering headline designed to make users click on the link, but with content rarely connected to the headline at all.

Cloaking: It is a process of providing different versions of a page to the crawlers.

Cloning: Creating a replica of websites or cards with intent to defraud.

Cloud Act: Cloud Act is the U.S. legislation related to the transfer of electronic data with provisions for obtaining data for evidence and prosecution and also regulating transfer for foreign governments.

Cloud Computing: A type of computing that relies on shared computing resources rather than having local servers or personal devices to handle applications.

CNI: Critical national infrastructure.

Cold War: Intense bipolar international competition for influence and control between the United States and the Union of Soviet Socialist Republics (USSR). It began at the close of the Second World War and continuing until Soviet-installed communist regimes collapsed in Eastern Europe in 1989 and the USSR itself disintegrated in 1991. This conflict was labelled cold because nuclear weapons made direct military combat between the two likely to result in mutual suicide through escalation to so-called mutual assured destruction. The US and the USSR and their allies and clients therefore competed indirectly through competitive interference in the internal politics of third actors. The Cold War established the template for international conflict between nuclear powers. The cause of US and Soviet conflict is still debated; some argue it was due to mutual fear, others argue that one or the other was bent on imperial expansion, and still others argue that both were bent on imperial expansion. The politically prevailing view in the US today is that the US prevailed over the Soviet Union in the Cold War. Consequently, American-dominated Cold War-formed institutions such as NATO are positive tools for international stability and peace. They should be expanded and adapted to changed circumstances.

Collapsology: A set of theories that assume Western societies are about to collapse, and that the global crisis is imminent.

Collectivism: A cultural value that stressed the importance of the group over individual goals and cohesion within social groups.

Commerical Cyberstalker: A perpetrator who engage in cyberstalking for the purpose of financial gain.

Computer Fraud and Abuse Act: This 1986 Act serves as a modification to existing laws seeking to address issues of deception within the cyber realm. Computer users must receive proper authorization and must not exceed boundaries of authorization.

Congress: A national legislative body, especially that of the US. The US Congress, which meets at the Capitol in Washington DC, was established by the Constitution of 1787. It is composed of the Senate and the House of Representatives.

Console: An entertainment system designed to play video games (e.g., Microsoft's Xbox or Sony's PlayStation).

Contact-Driven Offender: Online sexual offenders who seek face-to-face contact with their child victims to engage in physical sexual activity (Briggs et al., 2011).

Content Scraping: It is a process of lifting off the displayed content from various websites and using it somewhere else or displaying it on other websites.

Conversational Analysis: Study of the frame of the conversation with specific attention paid to interactive details (interruptions, reformulations).

Conversion: A visitor to an e-commerce site completes a desired monetary transaction such as buying product or signing up for a service or a membership or whatever expectations an e-commerce site is intended to achieve by having visitors to the e-commerce site. A visit converts to a monetary outcome.

Convolutional Neural Networks (CNN): A special type of neural networks used popularly to analyze photography and imagery.

Cookies: Small text files that are placed on a user's web browser as they visit a website.

Covert Communication: Communication through methods that are designed to make such communication undetectable or unsuspecting.

CPA: Cost-per-acquisition advertising model pays affiliates only for visitor traffic that generated an income for the e-commerce site.

CPC: Cost-per-click advertising model pays affiliates for each visitor that was re-directed to the advertiser's e-commerce site, immaterial of the financial outcome; even if the visitor does not buy any products.

CPM: Cost-per-mille advertising model pays affiliates for simply displaying an advertisement of the e-commerce site to a visitor to the affiliate's website. This model requires least interaction by a visitor.

Crawling: It is the process by which search engines gather online information through crawling robots by moving from one web page to another by the use of hyperlinks.

Crime: Any illegal action that is considered an offence and is punishable by law.

Crime-Fake News: Fake news content which commits a transgression within the legal system in Singapore that can warrant a fine, imprisonment, or both.

Criminal Justice System: A system inclusive of law enforcement, the courts, and correctional practices established to control crime and penalize violators.

Criminal Negligence: Reckless disregard for the lives or safety of other persons. In health care contexts, healthcare providers have a fiduciary responsibility for providing appropriate treatment to patients under their care. Many nations have laws that make overt negligence in the provision of healthcare a criminal offence.

Criminology: The critical and systematic examination of how laws are made, the means, modes and motives of criminal offenders, and the collaborative responses to criminal activities by the judicial system, policy makers and community stakeholders.

Critical Discourse Analysis: Field of research that compares the social role of the speakers and the scene of enunciation.

Cross-Site Scripting (XSS): Injecting malicious code to be displayed in the victim's web browser to steal the victim's credentials.

Crowdsourcing: The practice of hiring a (large) group of people (the 'crowd') to accomplish a certain task, usually a repetitive task that does not require special training but that must be carried out over a large amount of data.

Cryptocurrency: A digital currency in which encryption techniques are used to regulate the generation of units of currency and verify the transfer of funds, operating independently of a central bank.

Cryptography: A strategy for encoding data in a specific way with the goal that those for whom it is planned can peruse and process it.

Cryptology: A technique used to secure communicating of information, data and messages by implementing special protocols and algorithms aims to prevent other parties from reading and understanding the information transmitted.

Cryptomarkets: A cryptomarket may be defined as a platform for exchange of goods and services, both legal and illegal, on the dark web. They remain hidden from the world due to the use of anonymizing browsers such as TOR based on encryption techniques. Majority of the cryptomarkets undertake the sale and purchase of drugs.

Cyber: A broad term relating to or characteristic of the culture involving computers, information technology, and the internet.

Cyber Abuse: Online behavior that threatens, intimidate, harass, harm, or humiliate a person.

Cyber Hygiene: Cyber protective behaviours that people engage in whilst on the computer and internet, such as installing and updating anti-virus software.

Cyber Law: The legal system dealing with cyberspace and the internet.

Cyber Security: The section of information security, within the framework of which the processes of formation, functioning and evolution of cyber objects are studied, to identify sources of cyber-danger formed while determining their characteristics, as well as their classification and formation of regulatory documents, implementation of security systems in future.

Cyber Security Skills: Cyber security skills are those skills associated with ensuring the security of information technology (IT-generally referring to information storage and integrity) and operational technology (OT-referring to systems that control physical devices).

Cyber Sovereignty: This is a phrase commonly used in the field of internet governance to define the will of states to exercise and sustain control over the Internet domain within their own borders, including political, economic, cultural and technological activities. However, it is not clear how to apply this sovereignty concept to current international relations and international laws.

Cyber-Victimization: Cyber-victimization refers to the process in which others are victimized through the use of information and communication technologies.

Cyber-Vulnerabilities: A flaw in a computer system that can make the system vulnerable to attack. A cyber-vulnerability may also refer to any type of weakness in a computer system itself, in a set of procedures, or in anything that leaves information security exposed to a threat.

Cyberattack: A malicious and deliberate attempt by an individual or organization to breach the information system of another individual or organization.

Cyberbully: A person who directly or indirectly uses technology to reduce another person to a psychologically inferior state.

Cyberbullying: The act of bullying by using tools available on electronic devices which connect to the internet, messaging services, and others digital communication networks.

Cybercrime: The usage of the computer and its related technologies for the purpose of disrupting, with the motivation to gain financial gains or causing political, social, and psychological harm.

Cybercrime Legislation: The process of making laws regulating cybercrime.

Cybercriminals: Individuals who commit crimes via the internet.

Cybersafety: Is the safe and responsible use of Information and Communication Technologies (ICT). NetSafe's approach to cybersafety is founded on: Maintaining a positive approach about the many benefits brought by technologies. Encouraging the public to identify the risks associated with ICT.

Cyberspace: Cyberspace is the environment created by the tangible links (computers), intangible (application and services), and networks (internet and telecommunication).

Cyberstalking: A form of harassment where the cyberbully makes continuous threats and sends inappropriate messages to an individual in the form of text messages, instant messaging, social media, emails.

Cyberterrorism: The use of information and communication technology to cause grave disruption or pervasive fear.

Cyberwarfare: Cyberwarfare is an overt or covert action of states, non-state actors or state-backed attackers that includes various tactics and techniques, notably advanced persistent threats, phishing tactics, viruses like Stuxnet, botnets, Trojan horses, zombies, Metasploit, SQL attacks, Rootkit, Nessus, pharming, Wireshark and buffer overflows to target infrastructure, software systems, and governmental institutions of different parties.

Cyberworld: The world of inter-computer communication.

DAO: Is an organization represented by rules encoded as a computer program that is transparent, controlled by shareholders and not influenced by a central government.

Dapps: Decentralized applications (dApps) are applications that run on a P2P network of computers rather than a single computer.

Dark Web: A small part of the deep web that has been intentionally hidden and is inaccessible through ordinary web browsers. It is accessible through using specialized software to hide the internet protocol (IP) address to provide absolute anonymity to users. The dark web has become a haven for criminal activity.

Darkfield: All criminal cases, in a certain area, that are not known to the authorities.

Darknet: The hidden computer network typically used for illegal trading and forums to include illicit activities such as human trafficking.

Data Breach: A security incident involving unauthorized access to data.

Data Execution Prevention (DEP or W^X): A paradigm that dictates that memory pages can have either execute or write permission but not both. Data execution prevention prevents self-modifying code and also attacks on the code that runs by itself (by exploiting buffer overflows and similar attack forcing the code to rewrite itself). DEP is a critical feature in almost all modern operating systems.

Data Scraping: It is a process used to extract massive amount of data from websites in which the data is stored in local computer system or in structured database.

DDR: Disarmament, demobilisation, and reintegration.

Decipherment: The inverse of encipherment which is also an algorithm to change unreadable messages to readable messages.

Deep Web: The part of the web not a part of the surface web. It includes content inaccessible through the use of a search engine. These include private servers that only those with permission may access, intranets utilized by a variety of organizations, or even typical social media pages that users wish to keep concealed from the general public.

Denial of Service Attack (DDoS): The activities which disrupt the services of the computer rendering the computer usage ineffective for the user.

Developed Country: A self-governing country with advanced technological infrastructure, a developed economy as well as an advanced industry.

Developing Country: A country that is still seeking to become advanced in all spheres that is industrially, economically, politically, and socially.

Digital Age: The period in which smart machines are determinative in social life.

Digital Cage: Refers to an opinion that every moment of the lives of individuals is under surveillance in the digital age.

Digital Evidence: Information that is stored and transmitted on digital devices.

Digital Millennium Copyright Act (DMCA): A united state law that defines what constitute of fair use by the end-user and what constitutes as piracy or DRM violation. The DMCA criminalizes production of devices whose sole perhaps is breaking DRM.

Digital Psychology: It is a multidisciplinary (Behavioral Economics, Psychology, Digital Communication, and Information Technology) approach to psychology which integrates the study of human beings with the research on new technologies.

Digital Rights Management (DRM): A software subsystem designed to allow rightful users to use contents (games, media) they paid for and disallow illegal use of contents the user has not paid for. DRM is mainly designed to limit the end-user, and as such, DRM software is not liked by the users.

Digital Signature: A secure mathematical algorithm used to validate the credentials of digital documents and coded information associated with pre-approved signer to approve transactions.

Disclosure: The process of revealing something.

Discursive Ethos: Image of the self that appears during an interview or a discussion.

Disidentification: The disappearance of an individuals' real social identifications in the digital world.

Disinformation: False content that is deliberately fabricated and distributed.

DNS Pharming: Providing a fraudulent DNS mapping to direct a victim to visit a fake and malicious website.

Domain-Specific Search (DSS): The problem of building a (rudimentary or advanced) search engine over a domain-specific corpus. Domains of special interest in this article were illicit domains such as human trafficking, over which building such an engine is an especially challenging problem.

Drugs: A drug can be defined as any substance, chemical or natural, that is consumed for purposes other than medicinal and scientific.

E-Fencing: Selling stolen property on electronic platforms to make it look like normal electronic commerce.

Economic Growth: It can be defined as the increase in the capability of an economy to produce goods and services from one period to another. It can be measured either in nominal terms or in inflation adjusted real terms. Typically, GDP or GNP is taken as a measure of economic growth. In notational terms, GDP growth rate, g_t , AU54: Mathtype 7 where, t indicates the particular time point.

Elliptic Curve: A curve in two dimensions, which is known by its group property on points. It is widely used in cryptography due to its hard assumptions.

Elliptic Curves Digital Signature Algorithm (ECDSA): Is a mathematical cryptology technique used by digital currencies and Bitcoin to ensure the security of the peer-to-peer transactions using secret codes and keys.

Email Harvesting: The mechanism to obtain a large number of email addresses using different methods or techniques.

Email Spam: Unsolicited emails that are usually sent in bulk to nonspecific recipients.

Embodied Conversational Agent: Characters which are generated by informatic tools and they show properties which are specific of face to face human communication.

Emoji: A small digital image or icon used to express an idea, emotion, etc.

Empathy: The ability to understand or feel what another person is experiencing or feeling.

Encipherment: An algorithm used to convert a readable message into unreadable message. It is used in the field of security.

Encryption: The process of encoding a message or information in such a way that only authorized parties can access it using a decryption key.

Encryption-Decryption: An algorithm used to transform information to something random, meaningless and not readable, and then translate it back to something understandable.

Enron: A company in the United States which went bankrupt in 2001 due to accounting fraud. It has been dubbed the worst accounting scandal in history, and it was exposed through whistleblowing.

Entity Resolution: Entity resolution (ER) is the problem of algorithmically determining when two entities in a KG refer to the same underlying entity. For example, the same entity 'Barack Obama' may have been independently extracted from two webpages under names such as 'President Obama' and 'Obama'.

ETag: Entity Tag is a server-side identifier assigned to content for cache-control. The browser caches and sends the ETag on subsequent web requests, which allows the server to send the resource only if the server version has changed. ETag can also be used to track users uniquely, online.

Ethereum: Is an open software platform based on blockchain technology that enables developers to build and deploy decentralized applications.

Exploitation: Taking advantage of someone or something for personal gain.

Externalizing Difficulties: Includes children's and adolescents' failure to control their behaviors.

Fake News: Content that contains inaccurate, misleading, or fabricated information about current events, which is being distributed through different channels of communication such as print, broadcast, text messaging, or social media.

Fake Reviews: Product review produced with the goal of artificially improving (or damaging) the ratings of the product.

Fantasy-Driven Offender: Online sexual offenders who seek only online interactions with children; often marked by illicit messages, exhibitionism, and child pornography (Briggs et al., 2011).

Fear of Missing Out (FOMO): Some people are afraid to go offline in case they miss out on some exciting piece of news.

File-Sharing: Offering and transferring digital files via various channels of the internet, usually in a decentralized manner.

Filter: The implementation of KM strategy. A method used to separate the big data, data, information, or knowledge needed to make a specific decision from unneeded big data, data, information, or knowledge.

Firewall: A firewall is a network security system that allows or denies incoming and outgoing network traffic based on predetermined security rules.

Form Spam: It is a method of submitting web forms with unwanted information.

Fraud: A deceptive practice or series of acts that are designed to take advantage of individuals, systems, or other process for the benefit of someone else, usually for personal monetary gain.

Gateways to Cyber Abuse: Computer applications or apps, websites, social media networks, texting services and other communication modes which can digitally or electronically connect users to cyberspace (the internet).

GDPR: General Data Protection Regulation is a new set of rules governing the privacy and security of personal data laid down by the European Commission.

Generalized Method of Moments (GMM Estimation): It is a common method for estimation of the parameters in statistical models. Usually it is applied in the context of semiparametric models, where the parameter of interest is finite-dimensional, whereas the full shape of the data's distribution function may not be known, and therefore maximum likelihood estimation is not applicable. Using the moment conditions, the true parameter values are estimated. The GMM method then minimizes a certain norm of the sample averages of the moment conditions. It is applied in case when there can be a chance of endogeneity problem.

Ghostwriters: Individuals who conceal their true identities from detection by engaging in schemes intended to defraud.

Gini Coefficient: In economics, the Gini coefficient sometimes called Gini index, or Gini ratio, is a measure of statistical dispersion intended to represent the income or wealth distribution of a nation's residents, and is the most commonly used measurement of inequality.

Globalization: Increasing global awareness of economic, social and political interdependencies among states due to increasingly porous state barriers due to rapidly increasing commerce, finance, information and labor flows across these borders. Incentives to globalize ultimately relate to the imperative to develop a state's economic and political power resources through integration in the global capitalist production chain.

Global Platform: Is an organization that publishes the standard for secure mobile and embedded platform

Grey Zone Threats: These are the threats that comprise a full spectrum of means and tools used by aggressor states to subvert their rivals' plans and strategies. These kinds of threats are perceived as affordable, less risky and flexible by the aggressor states.

Grooming: Attempts by an adult to build a child's trust and interest before making sexual advances.

Hacker Culture: A subculture of individuals who abuse vulnerabilities in systems for a common goal.

Hacker Ethics: Principles and ideologies that are shared in hacker culture.

Hacking: Manipulation of a technological device to acquire data unlawfully within a system.

Hactivism: 1) The combination of 'hack' and 'activism' to explain the use of technology in the promotion of political or social change. 2) Political engagement around hacking activities and the access to free and independent information.

Hate Speech: Speech that attacks a group (or, sometimes, a person) based on categories like race, sex, religion, origin or disability. Its goal is to incite prejudice and spread bigoted views.

Health Research Fraud: Intentional misrepresentation of the methods, procedures, or results of healthcare research. Behavior characterized as scientific fraud includes fabrication, falsification, or plagiarism in proposing, performing, or reviewing scientific research, or in reporting research results. Health research fraud is unethical and often illegal. A good example of such fraud with major ramifications is the measles-autism link published in the lancet but retracted in 2010 when it was confirmed that the study was conducted dishonestly and irresponsibly, using bogus data. Nevertheless, this erroneous link is partly responsible for increasing refusals of Measles containing vaccines by parents.

Healthcare Fraud: An intentional deception or misrepresentation that the individual or entity makes knowing that the misrepresentation could result in some unauthorized benefit to the individual, or the entity or to some other party. Healthcare fraud refers to illegal acts of misrepresentation and false claims in order to receive undue financial or healthcare advantages. Health care fraud accounts for between 2 and 10% of wasted health resources globally. The World Health Organization cites healthcare-related fraud as one of 10 leading causes of inefficiency in health systems. Web-based healthcare fraud is a major challenge, especially when signatories to health organizations' accounts siphon money into private bank accounts. Regular audits and electronic monitoring systems such as e-claims management services help to monitor and prevent healthcare fraud.

HFI: Human freedom index; a numerical measure of the personal and economic freedom available in a country. It is measured annually. The HFI is determined from an evaluation of over 70 different indicators for each measured country.

Homebrew: Software that the end-user codes and/or compiles for his own (and his friends) device. This software is not suctioned by the device manufacturer who receives no royalties.

HPKP: It is a safekeeping policy that tells a web client to associate a detailed cryptographic public key with a certain web server to cut the jeopardy of MITM attacks with bogus certificate.

HRM: Acronym for human resource management. A set of practices to attract, develop, and maintain an effective workforce.

HSTS: It is a web safekeeping policy contrivance that aids to protect websites against protocol downgrade outbreaks and cookie hijacking.

HTML5: Version 5 of hypertext mark-up language which was released in October 2014 added major improvements and features such as ability to handle multimedia and graphic features natively, and a web storage framework that can store data similar to previous usage of cookies.

HTTP: HyperText Transfer Protocol, the underlying protocol used by the world wide web. This protocol defines how messages are formatted and transmitted, and what actions web servers and browsers should take in response to various commands.

HTTP Cookie: Due to security reasons, websites visited by an Internet user are not allowed to access the internal storage of the visitor's computer, such as the hard disk. The only way to store a small amount of data such as visitor's preferences, which is individual to each visitor is to store it within the browser's storage, as plain text. Such storage is called a cookie, which was in earlier browsers a text-based file on the visitor's computer. But now each browser decide how it stores. Though a browser may have many hundreds of cookies, each saved by a different website, each website can only access the cookie that it has placed, but not the cookies placed by another website.

Human Sex Trafficking: Inducing others to perform a commercial sex act by force, fraud, or coercion; as inducing a person under 18 years of age for such an act; and/or as recruiting, harboring, transporting, providing, obtaining a person for labor or services through the use of force, fraud, or coercion in order to subject them to involuntary servitude, peonage, debt bondage, or slavery (National Institute of Justice, 2012).

Human Trafficking: Modern day slavery or illegal transporting of people typically for the purposes of forced labor or sexual exploitation.

Hybrid Warfare: A recent term for reliance upon covert and informal policy tools for interference in the internal politics and policy making in target states. This term emerged concurrently with the development of the Internet as an infrastructure vehicle and as form of media communication. Covert and informal modes of international political competition and influence expansion acquired greater emphasis along with the post 1945 nuclear setting. The need to maximize the degree of control over potentially escalatory conflict dynamics pushed policy makers to obscure their international victories, defeats and stalemates in order to lessen the potential for provoking nationalist hostility that would lessen the political decisional latitude available to policy makers.

Hypercall: The term is analogous to System call. A call by a user process or the operating system for the hypervisor to perform some service required by the operating system of process.

Hypercomputation or Super-Turing Computation: Is a multi-disciplinary research area with relevance across a wide variety of fields, including computer science, philosophy, physics, electronics, biology, and artificial intelligence; models of computation that can provide outputs that are not Turing computable.

Hypervisor: A hypervisor is a type of computer software designed to run multiple operating systems on the same hardware.

Identification Warning Signs: Signs that showcase evidence of identifying with law enforcement, military paraphernalia, attackers, or assassin.

Identity Theft: The crime of stealing sensitive personal information, such as usernames, passwords, date of birth, social security number, and personal and financial information.

Illegal: Actions or practices which are against the law.

Indexing: The process followed by search engines to create an index of the contents present on the Internet, to allow easy retrieval when displaying results to user queries.

Individualism: The belief that each person is more important than the needs of the whole group or society.

Information and Communication Technology (ICT): Telecommunication technologies that provide access to information such as the internet, wireless networks, cell phones, and other communication mediums.

Information Extraction (IE): Information extraction (IE) is an algorithmic technique that generally accepts as input either text or raw HTML as input, and outputs a set of ontologically typed instances. For illicit domains, the investigative schema serves as the ontology. Supervised machine learning and deep learning IE methods have emerged as state-of-the-art in recent times.

Information Operations: Information operations are the part of political warfare/grey zone conflicts that occur in an asymmetrical way via social and conventional media, state organisations and military means to weaken the morale and psychology of enemy states.

Integrity: Being whole and having a consistent set of ethical, moral, and legal practices.

Internet: The Internet is an interactive medium based on a decentralized network of computers. The Internet may also be used to engage in other activities such as sending and receiving emails, money, trading files, exchanging instant messages, chatting online, streaming audio and video, every type of business purpose, and making voice calls.

Internet Blocking: Blocking access for users to certain Internet sites on a national level.

Internet Crime Complaint Center (IC3): It was established to provide people with a reliable and convenient reporting mechanism to submit information to the Federal Bureau of Investigation (FBI) regarding cybercriminal activities and to develop cooperation with law enforcement agencies.

Internet of Things (IoT): IoT is a concept of connecting any device to the internet or other connected devices to send and receive data.

Internet Privacy: This is the privacy and level of personal data and or information published online (via the internet).

Internet Utilisation: The amount of data flowing through a computer or device (mobile phone, tablet) for a given period of time.

Intimate Partner: A close personal relationship between individuals who identify as a couple that is characterized by some of the following dimensions: emotional connection, regular contact, and ongoing physical contact that need not be sexual.

Intrusion: Wrongfully accessing a computer's system or network.

Intrusion Detection Systems: An intrusion detection system (IDS) is a hardware device or software application that monitors a network or systems for malicious activity or policy violations.

Investigative Schema: An investigative schema is an ontology expressing an investigative domain of interest, usually involving an illicit activity like sex advertising. The investigative schema is usually simple and shallow, hence the term 'schema' and not 'ontology'.

IP Address: Internet protocol address, the basic identifier of a computer participating in the internet. It can be seen as a pseudonym of the user of the computer and can be connected to the identity of the user by his internet service provider.

IRC: Internet relay chat (IRC) is a system for chatting that involves a set of rules and conventions and client/server software.

Isolation: LCT step used more by contact-driven offenders to separate victim from support network.

Key Exchange: A method of transferring a secret key among various users. This key may be needed in cryptography to protect many entities like information, system, etc.

Knowledge Graph (KG): A knowledge graph (KG) is a directed, labeled multi-relational graph that is used to model and represent semi-structured data to make it more amenable to machine reasoning ('knowledge').

L4: A family of microkernel operating systems by Liedtke initially. OKL4 and seL4 are operating systems that were derived from L4.

Law of Armed Conflict: The Law of Armed Conflict (LOAC), also known as the International Humanitarian Law, is a body of international law which regulates the behaviours of actors during armed conflict by ordering balance between military necessity and humanity. It comprises the Geneva Conventions, Hague Conventions and customary laws. It also limits the targeted attacks of combating parties in order to protect civilians and avoid total disaster.

Leakage Warning Signs: Signs that show-case evidence of communication to a third party of an intent to do harm to the target.

Legislation: Law enacted by a legislature.

Legislature: A body of individual persons empowered to legislate; specifically, an organized body authorized to make laws for a political entity such as a nation, state or province, or a city.

Link Spamming: The process of posting links on websites, discussion forums, blogs, and other web services that show user comments.

Local Area Network (LAN): Computer network covering a small local area, like a home, office, or small group of buildings such as a home, office, or college.

LoM: Loss of money; personal cybersecurity spending attitude and behavior; the willingness to buy software products or services that enhance personal cybersecurity.

Loneliness: An unpleasant emotional response to isolation or lack of companionship.

Machine Learning: Is the use of artificial intelligence (AI) that provides systems with the capability to learn and automatically improve from experience (data) without being explicitly programmed.

Machine Learning Application: Is class of methods of artificial/natural intelligence, the characteristic feature of which is not a direct solution of the problem but training in the process of applying solutions to a set of similar problems.

Machine Learning Application With Avatar-Based Management Technique Use: Is a class of methods of natural intelligence, the characteristic feature of which is not a direct solution of the problem but training in the process of applying solutions to a set of similar problems.

Malicious Code: Computer code often used by hackers to infiltrate a computer to cause damage and security vulnerabilities.

Malspam: Spam emails that carry and deliver malware.

Malware: Malicious software that is designed to compromise a computer, server, or a computer network so as to gain unauthorized access or to cause damage.

Maoists: Maoists, also known as Naxalites or Naxals, are the group of people who believe in the political theory derived from the teachings of the Chinese political leader Mao Zedong. It is a doctrine to capture State power through a combination of armed insurgency, mass mobilization and strategic alliances. Also, these Maoists use insurgency doctrine based on use of propaganda and disinformation against State institutions. Herein, the author has used Maoists, left-wing extremists, and Naxalites interchangeably.

Masquerading: The creation of an anonymous or fake identity by an individual to harass another individual.

Maturity Models: Is a section of avatar-based management.

Metropolitan Area Network (MAN): A network that connects two or more local area networks together but does not extend beyond the boundaries of the immediate town, city, or metropolitan area.

Misinformation: False content that is the product of error (i.e., whose originator or distributor may not be aware that the content is not truthful).

Mobile Games: Digitally based games mostly played on mobile devices (e.g., smartphone, tablet) (DaCosta, Seok, & Kinsell, 2015).

Modchip: A hardware device that is soldered on top of existing product PCB replacing some chip. Usually, the modchip is designed to remove or disable the chip that handles copy protection.

Modus Operandi: The typical course of events in a criminal offence.

Money Laundering: The conversion of illegally obtained money to legitimate money and assets using legal businesses and transfer of currencies.

Monte Carlo Simulations: Monte Carlo simulation is a mathematical technique that generates random variables for modeling risk or uncertainty of a certain system. The random variables or inputs are modelled on the basis of probability distributions such as normal, log normal, etc. Different iterations or simulations are run for generating paths and the outcome is arrived at by using suitable numerical computations.

Mutual Legal Assistance (MLAT): MLAT are formal investigation request made by the states for the access of the data located in other country for the purpose of investigation and extradition.

Nation: A community which a nationalist believes should and can achieve national self-determination through acquiring a sovereign state for the nation if it does not already have such a state. If this community already has its own sovereign state, then the nationalist will be perceptually and emotionally preoccupied with challenges to this sovereign state, tending to equate the state, represented by its governmental apparatus, with the nation.

Nation State: A state in which the overwhelming majority of citizens show their primary self-identification with the territorial community within the state through favoring it more above any other identity group or community. Examples include the United States, Russia, China, Japan, Germany and others. Multinational states, such as the old Soviet Union and Yugoslavia as well as Iraq, are not nation states. Neither are multiethnic states nation states. Examples of the latter include most post-colonial African and many post-colonial Asian states including India. Non-nation states, and multinational states in particular, are subject to centrifugal political forces among ethnic groups seeking national secession and self-determination. These centrifugal forces may maintenance of liberal democratic political regimes highly problematic insofar as democratic elections produce ethnic nationalist leaders seeking self-determination. The communities of the old Yugoslavia as well as in the old Soviet Union continue to deal with such secessionist and irredentist nationalist forces.

Nationalism: A form of intense ingroup political loyalty opposing perceived challenges to the sovereignty of the nation. It is characterized by relatively intense emotional affect and perceptual stereotyping of self and other, outgroups stereotypically perceived as challenges to the nation. A community behaves nationalistically when the modal, politically attentive citizen is a nationalist.

Nationalist: An individual who sees himself/herself as a member of a large group of people who constitute a community that is entitled to independent statehood and who is willing to grant that community a primary and the primary terminal loyalty.

Netrespass: Infiltrating another internet user's space and carrying out unauthorised activities (e.g., trespass).

News Scraping: It is a process of scraping the news from the newspaper websites.

Nonconsensual Pornography: The distribution of sexually graphic images, including through digital platforms, of individuals without their consent. This is also referred to as “revenge porn,” “cyber rape,” and “involuntary porn.”

Normal World (Insecure World): The normal operating system that the given platform is running for normal applications. In most cases, this refers to Google’s Android or Apple’s IOS.

Normative Belief: Beliefs about the acceptability and tolerability of a behavior.

Object-Oriented Ontology: Object-oriented ontology (OOO) is a school of thought which argues that objects exist independently of human understanding and perception. The term was coined by the philosopher Graham Harman. It is also designated in the existing literature as ‘speculative realism’, which criticises the reductionism of Kantian philosophy.

Onion: A hidden Internet domain that disguises a site’s true Internet (IP) address. Onion domains are accessed using TOR, usually through a specially designed Internet browser.

Online Child Sexual Exploitation: Use of information technology including social media, webcams, or cell phones to solicit or coerce children to engage in illegal or inappropriate sexual activity.

Online Communication: Any kind of communication between either individuals or organisations that occurs on the internet.

Online Phishing: An online criminal attempt via fraudulent emails, web links, and websites to trick online users to surrender sensitive private information.

Ontological Approach to Cyberspace: It basically assesses cyberspace as a metaphysical laboratory that combines art and philosophy of things, machines and different domains, although this philosophical approach is not new.

Ontology: An ontology may be practically defined as a controlled set of terms and constraints for expressing the domain of interest. An ontology can range from a simple set of terms (e.g., {PERSON, LOCATION, ORGANIZATION}) to a taxonomy (with concepts and sub-concepts e.g., ACTOR and ENTREPRENEUR would be sub-concepts of PERSON) to a general graph with equational constraints e.g., that the domain and range of the relation starred-in is ACTOR and MOVIE respectively. Any KG that is ontologized thus should obey such constraints at the instance level.

Open Coding: The process of repeating readings of media sources and a line-by-line analysis of the data in order to open up the data to understand the meanings and concepts in it. Open coding includes the labelling of concepts and creating categories for comparison.

Optimism Bias: A human tendency where people overestimate the likelihood of good things and underestimate the likelihood of bad things happening onto them.

Panel Data: Also called longitudinal data, represents cross-sectional time series data i.e. data on multi-dimensional cross-sections (comprising of individuals, firms and countries) over a period of time.

Paper Mills: Business entities created for the sole purpose for selling scholarly works and publications written by ghostwriters.

Parental Mediation and Monitoring: The strategies that parents use to manage the relationship between their children and media.

Parenting Style: The standard strategies that parents use in their child rearing.

Patient Safety: Initiatives to assure freedom from accidental or preventable injuries produced by medical care. Emphasis is placed on the system of care delivery that prevents errors, learns from the errors that do occur, and is built on a culture of safety that involves health care professionals, organizations, and patients. With the expansion of internet technology in the use of medical devices such as cardiac pacemakers, patient safety is increasingly vulnerable to web-based attacks, which have serious repercussions.

Payment Gateway: An online service that facilitates cashless transactions.

Peer Attachment: The internalization of the knowledge that their peers will be available and responsive.

Peer Contagion: The transmission or transfer of deviant behavior from one adolescent to another.

Peer Support: A situational process in which respect and support principles characterize the relationships involving people with common experiences.

Peer-to-Peer: A distributed service whereby one person communicates with another, without intermediation by an outsider.

Peer-to-Peer Network: A network of nodes with usually equal rights and responsibilities. The nodes are usually computers of Internet users where a software with the peer-to-peer protocol is running.

Periodicity: Periodicity is the occurrence of similarity in more or less regular intervals and is a property exhibited by many processes that are of interest in a variety of scientific disciplines.

Personal Area Network (PAN): A network typically involving small devices organized around an individual person.

Perverved Justice: A grass-roots vigilante organization where volunteers pose as children online in order to expose offenders.

Phishing: A method of cyberattack which is employed to capture sensitive information including passwords and personal information for malicious purposes through means such as deceptive emails.

Plagiarism: Individuals who intentionally create and publish false information to gain an advantage or benefit.

Polarization: Intra-societal stereotyping due to intensifying perceived challenges from other constituencies within a polity, with the different contestants portraying the other as disloyal, even treasonous, to the nation and its state. Polarization is most likely to intensify when certain constituencies within the polity portray their favored policy prescriptions for the perceived well-being of the nation as religiously, i.e. divinely mandated. Secular opponents, therefore, are more likely to be stereotyped as evil and disloyal.

Police Force: A body of trained officers entrusted by a government with maintenance of public peace, law and order, enforcement of laws, and prevention and detection of crime.

Poverty Head Count Ratio: The poverty head count ratio (PHCR) is the proportion of a population that exists, or lives, below the poverty line.

Power: The exercise of influence over the minds and actions of others.

Predictive Analytics: Is the use of data, statistical algorithms, and machine learning techniques to identify the likelihood of future outcomes based on empirical data.

Price Scraping: It is a process of extracting or collecting the prices of various items in e-commerce site available over the internet without the consent.

Prior Ethos: Image of the self before the discussion (perception of the self by others).

Privacy: Ensuring privacy involves citizens having control over existing information about themselves and exercising this control in a consistent manner with their personal interests and values.

Privacy Paradox: Individuals often claim to be concerned about threats to their privacy, yet do not act to protect their personal information.

Privacy Protection: The coexistence of the collection and dissemination of information communication technologies, what the public expects as well as socio-political and legal concerns bounding them.

Private Browsing Mode: A privacy feature in web browsers that disables a user's browser and search history.

Private Cyberstalker: A perpetrator of cyberstalking for personal motives.

Private Health Data: Is defined as individually-identifiable health data, which is exquisitely sensitive. Being linked to an individual, the private health data can only be shared with the permission of the individual.

Privilege Ring: Intel architecture defines several privilege “rings” (protection rings) that refer to the current state of the system. These rings are ring 3 (user mode) where certain operations as not allowed, ring 0 (supervisor mode/operating system mode) where access to hardware devices is allowed, and hypervisor mode (ring –1) where hypervisor operations are allowed. Rings 1 and 2 also exist: these “in-between” privilege levels had historical usage but are mainly unused in modern systems.

Proof-of-Work: An algorithm used to affirm transactions and produce new blocks to the chain.

Protection Motivation Theory: This concept attempts to explain the way in which individuals react to perceived threats, and holds that individuals consider the perceived severity and probability of a threat, as well as the efficacy of their potential response.

Provictim Attitudes: The belief that bullying is unacceptable and that defending victims is valuable.

Pseudo-Child: A law enforcement officer or a volunteer posing as a child in a chatroom.

Public Sphere: The area of political and cultural discourse of the modern actor.

Query Reformulation: Query reformulation refers to a set of techniques wherein a query (in some domain-specific language like SPARQL or SQL) that is originally posed against a DSS engine is reformulated into a set of queries (in the same or different language) to increase query retrieval performance. Query reformulation is a useful technique both when the underlying KG is noisy and when the original query does not fully express (or over-conditions) user intent.

Raising Concerns Policy: Otherwise labelled “freedom to speak up” and “internal whistleblowing” such policies provide standardization of internal channels for speaking up about illegal or unethical practices and provide support and required anonymity for the employee who raises a concern.

Random Forest Classifier: Random forest classifier uses a set of decision trees from randomly selected subset of the training data and then aggregates the decision from each set to arrive at the final decision class of the test data. This improves accuracy and avoids over-fitting and hence better than decision tree algorithms.

Ransomware: Is defined as the illegal access to computer system using malware for the purpose of gaining control of the system with the motivation for financial gains.

Red Pill: Red pill is a type of software that is used to detect and defeat blue pills. The goal of the red pill is to provide an answer to the question, “Is the computer currently running a blue pill?” in the most reliable possible method.

Relational Ethics: A contemporary approach to ethics that situates ethical action explicitly in relationship. An important context of such relationships is within organizations, in which employees and employers have roles and responsibilities. Organizational policies and codes of conduct (and in some nations, anti-defamation laws) usually explicitly prohibit employees from discussing or exposing company secrets to the media or third parties without management approval. Thus, external whistleblowers are implicitly violating the relational ethics of such organizations.

Revenge Porn: Sexually explicit images sent or posted without a person’s consent; often used to intimidate or embarrass.

Rich Execution Environment (REE): Rich Execution Environment is another area inside the main processor. The Rich Execution Environment runs a separate operating system. Usually, Google’s Android or Apple’s iOS. The Rich Execution Environment refers to the standard operating system that the device is running. The Rich Execution Environment offers significantly more features and applications and as a result, is vulnerable to attacks.

Risky Online Behavior: A risky online behavior is an action that can potentially leave one exposed to a variety of dangers, putting individual and possibly organizational internet security at risk.

Romance Scams: Social media are used to establish a relationship of trust between the perpetrator and the victim. As soon as the victim transmits confidential pictures or videos to the perpetrator, the perpetrator abuses them for blackmail purposes.

Rootkit: Rootkit is malicious software that grants unauthorized user-persistent access to the victim computer resources. The rootkit is also designed to mask its existence such that the administrator will not be able to detect it.

Router: Router is an inter-networking device that forwards the packets from one computer network to another. Routers perform the traffic route finding on the Internet by means of a routing table.

RtoEx: Reluctance to express; the reluctance to freely express oneself online or on the internet.

RtoExC: Reluctance to express due to concerns of possible consequences or safety; the reluctance to freely express oneself online due to concerns of possible consequences or safety issues resulting from the expression.

RtoExnonC: Reluctance to express when users are not reminded of possible consequences or safety issues resulting from the expression.

Scam: A dishonest scheme used to deceive and manipulate a person into voluntarily providing valuable assets or information.

Scenography: Study of the scene frame (concrete location, definition of the setting).

Secure Communication: A method of transferring information on the internet securely.

Secure World: Secure world is the name for the secure, trusted execution environment (TEE) on ARM Architecture. It is running concurrently, on the same CPU as the normal world. However, ARM provides hardware and software mechanisms to ensure that the normal world and secure worlds are running on separate environments.

Security: A set of measures taken to protect oneself from any acts of violence, such as attacks, robberies, espionage, sabotage, etc.

Select Committee on Deliberate Online Falsehoods: In 2018, a Select Committee on Deliberate Online Falsehoods was set up by Singapore's parliament to examine and report on the phenomenon of the use of digital technology to spread falsehoods online. They have since unveiled 22 recommendations to combat online falsehoods.

Selective Coding: The process of further linking the categories from axial coding into a core category. This process takes place after axial coding.

Session Hijacking: Using a spoofed IP address or Man-in-the-Middle techniques to impersonate a legitimate host to eavesdrop or redirect network communication.

Sexting: A common practice among young persons, which involves taking sexually explicit images of one's self and sending it to others via ICTs.

Sextortion: A form of sexual exploitation during which the victim is coerced to provide sexual favors (including child pornography material) to the perpetrator.

Sexual Exploitation: Taking advantage of a person sexually for personal gain or make profit.

Shareable Content Object Reference Model (SCORM): Is a collection of standards and specifications for web-based electronic educational technology (also called e-learning).

SIEM: Security information and event management.

Signature-Based Classifier: Signature-based classifier classifies items based on an entry in a lookup table with signatures and the corresponding class labels. Hence, this classifier is not efficient in detecting novel patterns/signatures.

Singular Value Decomposition (SVD): A factorization mathematical algorithm of matrices used in diverse application such as signal processing, communication, and imagery.

Sleptsov Net (SN): Is a bipartite directed multi-graph supplied with a dynamic process.

Smart Contract: Is a computer code running on top of a blockchain containing a set of rules under which the parties to that smart contract agree to interact with each other.

Smuggling of Migrants: The facilitating of illegal entry of a person into a country he or she is not a national or resident of.

Social: Engineer: A person who is expert on the social engineering techniques, he uses deception to manipulate individuals into divulging confidential or personal information that may be used for fraudulent purposes.

Social Aberration: Diversion from common social values and norms.

Social Comparisons: As a result of using social networking sites some people may get the impression that other users are leading better lives in comparison to their own.

Social Engineering: The psychological manipulation of victims by cyber perpetrators, in order to get victims to divulge sensitive confidential information, or to perform certain actions that help perpetrators to successfully execute their cyberattacks.

Social Engineering Attack: Various manipulation techniques to elicit sensitive information, manipulating a person into giving information to the social engineer.

Social Exchange Theory: A behavioral theory that seeks to explain the interaction between a person and another person or entity. Its fundamental proposition is that the interaction is influenced by the person's evaluation of the interaction's risks versus rewards.

Social Exclusion: The process involving individuals or groups of people block or deny someone from the group.

Social Network: A social network is an online communication platform that is used for creating relationships with other people who share an interest, background or real relationship.

Social Network Security: The process of analyzing dynamic social network data in order to protect against security and business threats.

Social Networking Sites: Social networking sites (SNS) enable users to interact with other people online; similar to how people may socially interact offline by sharing personal experiences, images, making plans, and so forth.

Sociology of Crime: A science discipline that examines the phenomenon of crime through a sociological approach in its historical process.

Spam: Messages sent via the internet often unimportant with the intent to advertise, induce malware and phishing programs.

Spamming: It is an exploitation of messaging systems to broadcast unwanted messages.

Spear Phishing: Phishing for sensitive information by using personalized emails containing malicious attachments or fraudulent web links to target specific members or groups of an organization.

SSL: It is the foundation of the Internet protection. It secures website and handles the confidential and sensitive information of the users like credentials by providing critical security, privacy and data integrity.

Stalking: A person's location may be tracked without their knowledge or permission through the use of technology, by someone who is interested in their whereabouts or someone who holds a grudge; therefore, it is an invasion of personal privacy, ethically unacceptable, and potentially a safety threat.

Stateful Tracking: Using identifiable information stored in a user's local computer, such as an HTTP cookie to identify a visitor's computer uniquely on the internet.

Stateless Tracking: Does not store any identifiable information on a user's computer. A combination of unique signatures about each computer is stored in the tracking server, which can identify a computer with a relative high accuracy, but not as precisely as stateful tracking methods.

Steganography: A technique that aims to hide information or files inside an electronic file so that no one suspects such files or information is being delivered.

Stereotype: A simplified perception of the political environment, specifically regarding policy targets. Differences in stereotypical patterns in perception emerge along with different types of perceived challenges to the perceiver from a target. An intensely threatening target of perceived equal capability and techno-cultural level will tend to be perceived as a diabolical enemy. A perceived weak, inconsistent and unmanageable target unable to resist the perceiver's greater will and determination to achieve its objectives will tend to be perceived as degenerate. Dangerous adversaries perceived as superior in capability and techno-cultural capabilities will tend to be perceived as an imperial threat. Perceived weaker targets in capability and culture ripe for exploitation to achieve some other overarching objective, i.e. containment of a great power enemy, will be perceived as a colonial target of opportunity. Troublesome, threatening weaker targets in culture and capability will tend to be perceived as criminal rogues.

Surface Web: It can be defined as that portion of the internet whose websites are indexed by search engines such as Google, Yahoo, and others. They are easily accessible and do not require the use of special software as needed for the deep web.

TChS: Thinking about and changing settings; time considering two aspects of one's ICT device – contemplation of the device's cybersecurity aspects and whether time is consumed specifically for the checking and possibly changing of device settings that relate to security and privacy.

Technical Subterfuge: The act of deceiving victims and stealing their sensitive information by technical means.

Thin Hypervisor: A hypervisor that is designed to support only one operating system.

Third-Party Applications: An application that is provided by a vendor other than the manufacturer.

Threat: The possibility of malicious attempt to damage or disrupt a computer or system.

Threat Assessment: Threat assessment is a structured group process used to evaluate the risk posed by a student or another person, typically as a response to an actual or perceived threat or concerning behaviour.

TLS: The upgraded version of SSLv3.

TMT: Too much time; the belief that cybersecurity risk amelioration requires excessive usage of one's time.

TOR: The Onion Router is a free downloadable software that hides the IP addresses of computers via using multiple encrypted relays. Thus protecting user identity from traffic analysis.

Traditional Bullying: An escalating process in which one or more employees are subjected to negative psychological and physical abuse recurring over an extended period of time, where the target is reduced to a psychologically inferior state and it creates a hostile work environment to those exposed.

Traditional Face-to-Face Bullying: The use of strength or influence to intimidate or physically harm someone.

Trafficking in Persons: Human trafficking or the recruitment, transfer, transportation, or harboring of people by coercion or force, abduction, fraud, deception.

Transhumanism: Ideology that promotes the development of human beings through their interaction with artificial intelligence.

Trusted Computing (Trusted Systems): Trusted systems are systems that are supposed to behave in a certain predefined way (for example, verify DRM). Local and remote software can attest that the system is indeed a trusted system before executing code.

Trusted Execution Environment (TEE): A Trusted Execution Environment (TEE) is a secure area inside the main processor. The trusted execution environment runs a separate operating system in parallel to the main operating system in an isolated environment. The trusted execution environment guarantees the confidentiality and integrity of the code and data loaded in the TEE.

Trusted Platform Module (TPM): The Trusted Platform Module (ISO/IEC 11889) is an international standard and specification for a secure cryptoprocessor. The TPM is a dedicated microcontroller designed with hardware obfuscation to prevent tampering. The TPM provides cryptographic operations and can measure the CPU and running software for platform attestation.

TrustZone™: An ARM Exception level that allows running TEE in a secure environment in parallel to the normal ARM environment.

UN: United Nations.

Unethical: Actions or practices deemed immoral or wrong.

USA Patriot Act: The Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act of 2001 which granted the federal government increased control in monitoring and interrupting networks in order to counterbalance terrorist attacks.

User Account: An established technique for connecting a user and an information service.

Veracity: Conformity to facts; accuracy. Veracity is often difficult to establish in whistleblowing contexts since most whistleblowers have only limited information on a specified issue. Consequently, a significant proportion of external whistleblowing incidents have been found to be false. Contemporary whistleblowing laws such as the 2019 law in Australia require whistleblowers to provide objective evidence as condition to raising concerns internally or externally.

Victim: The individual or entity that suffers the effect of cyberattacks.

Video Games: Digitally based games typically played on personal computers or dedicated gaming devices, such as game consoles (e.g., Xbox, PlayStation) or handheld game devices (e.g., 3DS, Vita) (DaCosta et al., 2015).

Violent Extremism: A willingness to use or support the use of violence to further particular beliefs, including those of a political, social, or ideological nature. This may include acts of terrorism.

Virtual Child Pornography: Child pornography produced by digitally modifying pre-existing images or fully generated by a computer.

Virtual Circuit: Virtual circuit is a path for the flow of data packets over a network, which does not exist in reality. It is ‘virtual’ in the sense that there is no dedicated physical layer link between the source and the destination of the data.

Virtual Private Network (VPN): A virtual private network (VPN) provides a means of connecting to a network within an organisation (as if you were inside the organisation) even though you are not physically present.

Virtual Reality: A virtual environment that simulates reality in which human being can be immersed through tools like glasses and visors. Depending upon different tools, the user can receive and respond to different stimuli.

Virtue Ethics: Person rather than action based ethical conduct. It analysis at the virtue or moral character of the person carrying out an action, rather than at ethical duties and rules, or the consequences of particular actions. When morally orthodox and benevolent, virtue ethics is closely aligned to the ethical principle of deontology – fulfilling a virtuous moral duty. Many whistleblowers claim that their decision to expose alleged wrongdoing in their organizations were motivated by the desire to act according to their moral character to prevent harm to innocent others.

Vulnerability: It is defined as a defect, imperfection, weakness, or inadequacy of a system.

Warez: Term for illegal digital goods, usually software or multimedia files.

Warning Signs: Warning signs are acts which constitute evidence of increasing or accelerating risk.

Web Scraping: The process of extracting data from the websites in a systematic manner.

Web Spoofing: Using fake websites to phish and trick users into giving up their personal information.

Whaling: A special type of spear phishing that targets high-rank individuals such as executives of an organization.

Whistleblower: An individual who reveals wrongdoing to some higher authority. Illegal and unethical activities are usually revealed by such a person.

Whistleblowing: Non-obligatory act of disclosing information about unethical or criminal activity in an organization. Internal (intra-organizational) whistleblowing is less damaging to organizational credibility and the careers of whistleblower than external whistleblowing – reporting to the media or anti-corruption or institutional ethics boards. The term whistleblower comes from the whistle a referee uses to indicate an illegal or foul play. Ralph Nader coined the phrase in the early 1970s to reduce stigmatization of individuals who report illegal activity, any of whom were at the time referred to as “rats” and “snitches”. There are no public cases of cybersecurity whistleblowers on record to date, but in countries like the United States where large organizations have minimum mandatory cybersecurity requirements and payments of up to 30% may be received for whistleblowing acts which lead to recovery of assets from the Securities and Exchange Commission, a strong potential exists for such cases to emerge.

Wide Area Network (WAN): A group of computer networks connected together over a large geographical distance crossing metropolitan, regional, or national boundaries.

Wi-Fi: Wireless Fidelity, a standard technology for wireless access to local networks. This technology allows electronic devices to be connected to a wireless local area network (WLAN) and Internet using radio waves.

Winmax: Technology that allows the expansion of the internet signal at higher speeds over long distances.

Workplace Cyberbullying: An escalating process in which an employee is subjected to perceived psychological abuse recurring over a period of time where the perpetrator uses some form of technology.

World Wide Web: The world wide web (WWW) is a network of online content on the Internet that allows documents to be connected to other documents by a link and enable the user to search for information by browsing on the net.

Zigbee: Protocol that is employed for PANs and is based on the IEEE 802.15 standard. Even though they are low-powered, Zigbee devices can transmit data over long distances by passing data through intermediate devices to reach more distant ones, creating a mesh network.

About the Contributors

Mehdi Khosrow-Pour, D.B.A., received his Doctorate in Business Administration from the Nova Southeastern University (Florida, USA). Dr. Khosrow-Pour taught undergraduate and graduate information system courses at the Pennsylvania State University – Harrisburg for almost 20 years. He is currently Executive Editor at IGI Global (www.igi-global.com). He also serves as Executive Director of the Information Resources Management Association (IRMA) (www.irma-international.org) and Executive Director of the World Forgotten Children Foundation (www.worldforgottenchildren.org). He is the author/editor of more than 100 books in information technology management. He is also currently the Editor-in-Chief of the *International Journal of E-Politics (IJEP)* and the *International Journal of Semiotics and Visual Rhetoric (IJSVR)*, and is also the founding Editor-in-Chief of the *Information Resources Management Journal (IRMJ)*, *Journal of Electronic Commerce in Organizations (JECO)*, *Journal of Cases on Information Technology (JCIT)*, and the *Journal of Information Technology Research (JITR)*, and has authored more than 50 articles published in various conference proceedings and scholarly journals.

* * *

Fernando Luís Almeida has a PhD in Computer Science Engineering from Faculty of Engineering of University of Porto (FEUP). He also holds an MSc in Innovation and Entrepreneurship and an MSc in Informatics Engineering from FEUP. He has around 8 years of teaching experience at higher education levels in the field of computer science and management. He has also worked for 15 years in several positions as software engineer and project manager for large organizations and research centers like Critical Software, CICA/SEF, INESC TEC and ISR Porto. During that time, he had the chance to work in partnership with big international organizations and universities in several European projects. His current research areas include innovation policies, entrepreneurship, software development and cyber security.

Bede Ravindra Amarasekara is currently pursuing his PhD at Massey University in New Zealand. Having spent many years in the industry as a Software Developer, his current research interests are in web-based technologies.

Athanasios Anastasiou received his Bachelor degree in Electrical & Electronic Engineering from the University of Newcastle Upon Tyne, in 2005. In 2006, he received his M.Sc. degree in Digital Signal & Image Processing from the University of Central Lancashire. Likewise, in 2009 he obtained his second M.Sc. degree in Biomedical Engineering held by the University of Patras and the National Technical University of Athens (N.T.U.A.). In 2015, received his PhD degree in Biomedical engineering in the field

About the Contributors

of mobile health. Since 2011, he is a member of the Biomedical Engineering Laboratory of N.T.U.A.. His current research interests comprise Bioinformatics, Biosignal Processing, Digital Image Processing and technologies for assisted living. He is a Member of the Institute of Electrical and Electronics Engineers (IEEE) - EMBS Society and Computer Society, Member of the Institution of Engineering and Technology (IET) and a member of the Technical Chamber of Greece (TEE).

Thelma Androutsou is a PhD Candidate at Biomedical Engineering Laboratory, National Technical University of Athens.

Christopher Anglim works at both the University of the District of Columbia and the Washington College of Law at American University. He has a longstanding interest in the areas of Constitutional Law, Legislation, Jurisprudence, Cyber Law, and Privacy Law. He has written several books and articles, including a major encyclopedia on privacy law.

Fardaus Ara graduated in Public Administration from Dhaka University, Bangladesh. She did her MPhil from Bergen University, Norway and PhD from Murdoch University, WA. She joined Bangladesh Palli Karma Sahayak Foundation, an apex micro-finance organization, as a deputy manager in 1996. She is serving Rajshahi University as an academic since 1998.

Sandal Azhar has completed her graduation in Physical Science (Electronics) from Andc, University of Delhi and also holds a Post graduate degree in Electronics from Jamia Millia Islamia. She is currently pursuing Post Graduate Diploma in Cyber Security and Law from Institute of Cyber Security and Law, University of Delhi.

Antonio Badia is the author of more than 50 peer-reviewed papers and the recipient of several NSF research grants, including the prestigious CAREER Award. He is also the author of “The Information Manifold”, forthcoming from MIT Press. At the University of Louisville, he founded and directs the Database Research Lab.

Liudmila Baeva is Full Professor, Doctor of Philosophy, Dean of the Department of Social Communication, Professor of the Chair of Philosophy of Astrakhan State University. Author of over 220 articles and 6 monographs. Research interests focus on the field of axiology, philosophical anthropology, and the study of the information society issues. A member of the editorial board of the international journal “Socioloska luca: Journal of Social Anthropology, Social Demography & Social Psychology” (Montenegro) and the editorial board of the international journal “The Caspian Region: Economics, Politics and Culture” (Russia). Visiting Professor of Philosophy at Moscow State Technical University (Russia, 2005), Hainan University (China, 2007), South Kazakhstan State University named after M. Auezov, (City of Shymkent, Kazakhstan, 2011). Participated in the World Congresses of Philosophy in Istanbul, Seoul, and Athens.

Leroy Baldwin is an associate professor of Criminal Justice at Atlanta Metropolitan State College in Atlanta, Georgia, USA. He received a B.S. in Political Science from Florida A&M University and the Doctor of Jurisprudence degree from John Marshall Law School. In addition to having practiced law, he has also served as a high school teacher and has been published in Who’s Who Among America’s Teachers four times.

Aakash Bali is B.Tech Student at JayPee University of Information Technology, Solan, India.

Himani Bansal is B.Tech Student at Jaypee University, Solan, India.

Simone Barbato is a Clinical Psychologist. Graduated in Clinical Psychology with the thesis: “Digital psychology as a support for the person”, he specialized in “Human Performance Psychology” in Turin. He earned a Master in “Human Resources Management and Administration”, with the thesis “Virtual Reality and Employer Branding: from innovation to new selection standard”. He is Co-founder of IDEGO - Digital Psychology and Professor of Sport Psychology at University of Cassino.

Nii Barnor Jonathan Barnor is doctoral researcher in the University of Ghana Business School. He has a masters degree in management information systems and a bachelors degree in linguistics and music. His research interests are cybercrime, information systems security, information systems adoption, ICT for development, digital mobile maps and digital technologies.

Maria Basdeki is a lawyer, member of the Chalkida Bar Association, currently working for the Greek NGO Allilengyie/SolidarityNow in Athens, Greece. The main objective of work is providing assistance to vulnerable groups of people and participating in advocacy schemes for supporting their rights.

Punam Bedi is a Professor in the Department of Computer Science, University of Delhi since March 2007. She worked as officiating Director, Delhi University Computer Centre from Oct. 20, 2017 to April 16, 2018. She was the Head of Department of Computer Science, University of Delhi during Oct. 2005 - Oct 2008. She also worked as the acting Director, Delhi University Computer Centre from June 26 to Oct. 23, 2009. Before joining the Department of Computer Science, University of Delhi, she worked as a Lecturer/ Reader in the Deshbandhu College, University of Delhi from January 1987 to January 2002. She did her Doctorate in Computer Science from University of Delhi in 1999. She did her M.Tech. in Computer Science from IIT Delhi in 1986 and M.Sc. in Mathematics from IIT Delhi in 1984. She is mainly working in the area of designing and developing intelligent systems. She is using multi agent systems for the development of Intelligent Systems. Fuzzy Logic, Trust and Web Mining are the main techniques used for personalization of these systems based on users’ interests.

Monica Bell is a Neuroscience & Behavioral Studies and Philosophy major from the University of Notre Dame class of 2019.

Vladlena Benson is a Professor of Information Systems at Aston Business School. She is a specialist in technology governance, risk and compliance (GRC) and a Government Communications Headquarters (GCHQ)-certified Cyber Security Risk Management Frameworks practitioner. She is currently working with UK businesses on privacy and cyber security initiatives, such as the forthcoming General Data Protection Regulation (GDPR) and privacy compliance. Prof Benson’s research areas cover: information privacy; cyber victimisation; gender and culture differences in online behaviour; digital rights and the cyber vulnerability of young people. Her work also relates to religious orientation, digital behaviour and privacy on social media. She is a strong advocate for increasing diversity in the cyber security work force, and actively endeavours to bring more female talent into the digital economy. As part of her research, she currently runs a number of projects to help target the digital skills crisis – developing tools

About the Contributors

for opening up cyberspace entrepreneurship opportunities from an early age. As a result of her work in this area, Prof Benson was recognised at the Women in IT Awards 2017 for helping the development of career opportunities for women in cyber security.

Richard Boateng is an Associate Professor of Information Systems at the University of Ghana Business School. Richard's research experience covers digital economy, e-business, internet banking and social media. His papers have been published in or are forthcoming in the International Journal of Information Management, Internet Research, Qualitative Market Research: An International Journal, and many others.

Roman Brandtweiner is professor at the University of Economics and Business Vienna. His main research interests lie in the field of technology and society and green IT issues.

Frederick Edem Broni Jnr holds an MPhil degree in Management Information Systems and also a Teaching Assistant at the Operations and Management Information Systems Department (OMIS), University of Ghana Business School (UGBS). His background is in Computer Science and Management. His research interests are in Blockchain, Cryptocurrencies, Cloud Computing, Online Security and Privacy, and E-learning.

Joshua E. Byrd is a native of Atlanta, Georgia, USA. His professional career includes work as a criminal justice subject matter expert and staff attorney for a multinational litigation company. He currently serves as a Program Chair and Professor of Criminal Justice at American Intercontinental University. He is a former deputy sheriff and an eight-year U.S. Marine Corps veteran. His research interests include, cybercrime, the school-to-prison pipeline, environmental justice and crime prevention through environmental design. He obtained his Bachelor of Science in Criminal Justice from Georgia State University, his Master of Science in Criminal Justice from the University of Cincinnati and his Doctor of Jurisprudence from North Carolina Central University, School of Law.

Muhammed Can holds BA in Economics from Selcuk University (Turkey), MA in International Relations from Swansea University (UK), PGCert in International Affairs from King's College London (UK) and Advanced Certificate in Terrorism Studies from University of St. Andrews (UK). Currently, he is a PhD candidate at University of Minho (Portugal) in Political Science and International Relations. His research interests comprise Artificial Intelligence, Hybrid Warfare, Chinese Foreign Policy, Emerging Technologies, the US-China relations.

Chiam Chooi Chea obtained Bachelor Economics (Honours), Masters in Business Administration (MBA) and PhD (Economics) in 2001, 2003 and 2014 respectively. Since early 2003, she started her lecturing in an international private university college and private university in Malaysia with a total academic experience of approximately 13 years. Her field of research interest is in the field of resource economics and the trend of open distance learning (ODL). She is currently affiliated with Open University Malaysia under OUM Business School based in Bangi Learning Centre, Selangor.

Xingyu Chen is a Behavioural Sciences Research Analyst at the Home Team Behavioural Sciences Centre. Chen's research is in the areas of resilience, safety and security psychology which is supplemented by his background in communications. He has researched the psychological factors driving the spread of information during situations of high uncertainty such as scares and conflicts. As a Behavioural Sciences Research Analyst, Chen has presented to Home Team officers, community leaders, and Home Team psychologists on a variety of topics such as fake news and resilience to terror attacks. He has also presented about resilience on the day after terror incidents at Safety, Security Watch Group (SSWG) seminars to institutes of higher learning as well as industry partners. His current research interests include online misinformation, social resilience, individual crisis preparedness, and sentiment analysis.

Vassilia Costarides has graduated from National Technical University of Athens, from the school of Mining and Metallurgical Engineering with a specialization in Materials Engineering. She proceeded her studies in Biomedical Engineering and has worked in the medical device industry for 6 years as a technical specialist. Since 2013 she has been participating in projects regarding public health, medical device nomenclature, health technology assessment and medical device technical specifications. Among her interests is also quality in health care and she is an ISO9001:2008 and ISO13485:2003 auditor. She is currently a PhD candidate in Biomedical Engineering in the National Technical University of Athens and a member of the Biomedical Engineering Lab and Applied Informatics in m-Health research team. She is also a member of the Technical Chamber of Greece.

Charles Crowell is a professor in the Department of Psychology. He also directs the Computing & Digital Technologies Program, an information technology-related minor in the College of Arts & Letters. Along with his empirical and theoretical work on basic mechanisms of learning and motivation, Prof. Crowell has been involved for some time in applications of psychology and technology to learning, productivity, and performance improvement in organizations. As part of this work, he has investigated how technology can be used to augment human performance in various learning and work settings. Prof. Crowell oversees the eMotion and eCognition lab at Notre Dame that is devoted to investigating a spectrum of psychological phenomena ranging from the basic mechanisms underlying human movement and imitation to the ways in which humans interact with and are influenced by modern technological tools and devices.

Boaventura DaCosta holds a Ph.D. in instructional technology, an M.A. in instructional technology/media, instructional systems, and a B.S in computer science from the University of Central Florida. His research is interdisciplinary, concentrated in the fields of computer science and instructional design, with a special interest in games and learning.

László Dornfeld finished law school at the University of Miskolc in 2015 with a cum laude degree. He won two first prizes at the National Conference of Scientific Students' Associations before graduation. He started his PhD after that, researching the topic of cybercrime investigation under the supervision of Prof. Dr. Erika Róth. He worked for the National Bureau of Investigation's Department of Cybercrime as a scientific intern for six months in 2016. He joined a Hercule III project at the University financed by EU's OLAF in 2018 about the criminal law protection of the EU's financial interests, researching the topic of money laundering in cyberspace. He finished his PhD course in 2018 and since then he is a

About the Contributors

doctoral candidate. In 2019, he joined the government agency Ferenc Mádl Institute of Comparative Law as a researcher. He is an organizing member of the PhD Section of the Hungarian Society of Criminology.

Ramanujam Elangovan has received his M.E. from Anna University, Chennai, Tamil Nadu. He is pursuing his research in the area of biomedical engineering. His current area of interests are Data Mining, Time Series Mining and Biomedical processing. He has also published papers in national and international conferences and journals.

Aaron C. Elkins is an Assistant Professor in the department of Management Information Systems and Director of the SDSU Artificial Intelligence Lab. His research focuses on developing AI models that fuse physiological and behavioral sensor data to predict human emotion and deception. Elkins conducts experiments investigating automated deception detection in the laboratory, borders, and airports. Complementary to the development of advanced AI systems is their impact on the people using them to make decisions. He also investigates how human decision makers are psychologically affected by, use, perceive, and incorporate the next generation technologies into their lives.

Verity Er is a Behavioural Sciences Research Analyst at the Home Team Behavioural Sciences Centre under the Ministry of Home Affairs Singapore. Together with a team of researchers, Verity explores how crises, such as violent extremist attacks, can adversely impact social cohesion. She is also a trainer for Home Team officers on how to handle race and religious issues in the workplace, and has presented at HTBSC's workshop on fake news. Verity is currently pursuing an MSc in Applied Psychology.

Julie Exposito is founder and CEO of Musicology Studio where she has developed an adaptive learning system based on students' learning and cognitive styles. She has implemented successful sequential programs with a focus on skill and experiential based curriculum design to serve diverse students of all ages and individuals with varying exceptionalities and special needs. Dr. Exposito has served as the English language program coordinator for the Florida Association of International Educators and on the faculty at Miami Dade College and Broward College, teaching English for Academic Purposes with a focus on language acquisition and international conflict resolution in a classroom of linguistically and culturally diverse adult learners. Dr. Exposito completed a Doctor of Education with a concentration in Higher Education Leadership and Organizational Leadership from Nova Southeastern University and a Master's in TESOL from Florida International University. She received a Bachelor of Science in Education and French from Skidmore College. Dr. Exposito continues to write articles on education, higher education, the international student, learning styles, academic integrity, academic writing, leadership, and organizational stress.

Leyla Gamidullaeva graduated from Penza State University, the Faculty of Economics and Management, getting qualifications of an economist. L. Gamidullaeva got her PhD in Economics from Penza State University of Architecture and Construction in 2010 followed by the title of associate professor in 2018. Now she is associate professor at the department of management and economic security of Penza State University. Currently, L. Gamidullaeva is doing her doctoral research in the regional innovation system management at St Petersburg State University. She has authored more than 200 refereed publications and over ten books in innovation management, regional economic growth, networking and collaboration.

Suraj Gangwar has done Masters in Mathematics from National Institute of Technology, Jalandhar. He is currently pursuing Post Graduate Diploma in Cyber Security and Law from the University of Delhi. He is a technology enthusiast. His interest lies in cybersecurity and cryptography.

Giulia Gargaglione has a Master Degree in Well-Being Psychology from Catholic University of Milan. She currently works as a consultant. Her approach is based on positive psychology, that is, the scientific study of optimal human functioning and flourishing. Instead of drawing on a “disease model” of human behavior, it focuses on factors that enable individuals and communities to thrive and build the best in life. Her main professional focus is on Psychology applied to new technologies. In particular, her main area of intervention regards technology adoption. Other areas of intervention pertain change management, IT consulting and training, HR learning and development.

Dimitra Giannouli is a Software Developer and has been member of the Computer Solutions SA's Research & Development Department since 2018. She has graduated from the Department of Digital Systems of the University of Piraeus, specializing in Development of Digital Services. During her Bachelor studies, she focused her research efforts on e-Health and Mobile Health sector and she participated in the research and implementation of innovative Mobile Health mechanisms powered by 5G Network Slicing.

Anteneh T. Girma received a PhD degree from Howard University in Computer Science /Cyber Security. He has also received his M.Sc. degree in Systems and Computer Science from Howard University, and he received his B.Sc. degree in Mathematics from Addis Ababa University. He has many years of cyber security consultancy and teaching experience, and served as the Director of Information Technology at Howard University. Currently, Dr. Anteneh T. Girma is an Associate Professor of Cybersecurity and Forensics at Robert Morris University. His research interests are in the area of Cybersecurity and Information Assurance, Cloud Computing and Security, Digital Forensics, IOT Analytics and Security, Cryptography, and Machine Learning. He is also currently serving as a technical reviewer of research papers on different Cybersecurity tracks for major annual international conference in information technology. Among the awards he had received include the best research paper of the conference award on international information technology conference and recognition award for outstanding research and academic achievement.

Pamela Goh is a Behavioural Sciences Research Analyst with the Home Team Behavioural Sciences Centre (HTBSC). As a research analyst, her individual research portfolio is encapsulated by the resilience theme, and it includes crowd psychology and cyber hygiene. In essence, she is interested in understanding what contributes to the individual, community, and national's resilience in the event of a crisis from these perspectives. A key research area that Pamela looks into is the role of non-governmental organisations in the event of a violent extremist attack, and how civil societies in general can contribute to and complement Singapore's governmental efforts. Together with her team in HTBSC, the other areas that she has looked into are Singaporeans' perceptions to national resilience, cyber resilience, and fake news. Apart from resilience, Pamela is also interested in and has helped to write research papers that are terrorism-related. In addition to research, she also conducts seminars and trainings for government stakeholders, community leaders, and private companies. Pamela also holds other appointments in HTBSC, including being an internship manager for HTBSC's internship programme, as well as a Victim

About the Contributors

Care Officer (VCO) under the Singapore Police Force. She is currently doing her Ph.D at the Nanyang Technological University.

Dylas Gudoshava studied Library and Information Science. Area of specialism includes Information Service Provision in the fields of Law, Health, Humanities and Social Sciences; Research and Publication; as well as Marketing of Information Products and Services.

Daya Sagar Gupta received his Ph.D. in Computer Science and Engineering and M. Tech in Computer Application with distinction from Indian Institute of Technology (ISM), Dhanbad, Jharkhand, India. He received his B. Tech in Computer Science and Engineering from UPTU Lucknow (UP), India. He is currently working as an assistant professor in the department of Computer Science and Engineering, Shershah College of Engineering Sasaram, Bihar, India. His research interest includes Information Security, Lattice-based Constructions and Cyber Security.

Neha Gupta is a research scholar at Department of Computer Science, University of Delhi. She completed her MCA (Masters in Computer Application) from Department of Computer Science, University of Delhi in 2017 and later did 6 months internship at Proptiger Realty Pvt Ltd in analytics and search engine optimization. Before her post-graduation, she did her BSc. (Computer Science) from Keshav Mahavidyalaya, University of Delhi in 2014.

Laura Pinto Hansen received her Ph.D. from University of California Riverside where within her degree in sociology, she specialized in criminology and large-scale organizations. Her primary research interests have included white collar financial crimes, having had an earlier career within the taxes and financial planning fields. Her current research is focused on cybercrime. With a sabbatical planned in 2020, she is planning to explore emergency management and responses to cybercrime and attacks.

Richard Herschel is a Professor in the Department of Decision & System Sciences Department at Saint Joseph's University. This department offers programs in Business Intelligence & Analytics at both the undergraduate and graduate levels. Before becoming an educator, Dr. Herschel worked at Maryland National Bank, Schering-Plough Corporation, Johnson & Johnson, and Columbia Pictures as a systems analyst. Dr. Herschel has researched and written extensively about knowledge management and business intelligence. He is the founding Editor of the International Journal of Business Intelligence Research and he served as the Educational Channel Expert for b-eye-network.com.

Bogdan Hoanca is a Professor of Management Information Systems at the University of Alaska Anchorage. Before joining UAA, Prof. Hoanca co-founded, started up and sold a company that builds components for fiber optic communications. He also helped start and consulted with a number of other start-up companies in optical fiber communications. Bogdan received a PhD in Electrical Engineering from the University of Southern California in 1999, an MS in Electrical Engineering from Syracuse University and an Electronics Engineer degree from the Polytechnic Institute of Bucharest, Romania. His current research interests revolve around information security and societal implications of technology.

Rumenigue Hohemberger is a Lecturer at the Federal Institute of Science, Education and Technology Farroupilha (IFFar, Alegrete, RS, Brazil). He holds BS degree in Computer Science from the

Federal University of Pampa (UNIPAMPA, Brazil, 2011) and Specialization (2017) in Computer Networks. Cisco Certified Network Associate (CCNA) Instructor. His primary research interests include IoT networking and security.

Edith Huber is a senior researcher at the Danube University Krems. Her research focuses on Cyber Security, CERTs, Information Security, Communication, Cybercrime, Cyberstalking, New Media, Social Science and Criminology.

Marisa Hultgren holds a Master of Science in Homeland Security from San Diego State University and a Bachelor of Arts in History and Geography with a concentration in Geographic Information Systems from California State University, Stanislaus. The main context of her research has been that of counter sex trafficking with an emphasis on the detection of victims through text mining of online data. She currently works in Southeast Asia in the humanitarian field of education to support at risk communities in impoverished, rural villages.

Farida Jaha is a PhD student at the LTI laboratory at ENSA El Jadida, Chouaib Doukkali University. He does his research in the field of computer security and more precisely access control of the BYOD environment.

Helge Janicke is the Head of School of Computer Science and Informatics at De Montfort University, UK. His interests are covering formal verification techniques and their application to Cyber Security, SCADA and Industrial Control System Security as well as aspects of Cyber Warfare. He is working closely with Airbus Group and established DMU's Airbus Group Centre of Excellence in SCADA Cyber Security and Forensics Research in 2013. He is a general chair of the International Symposium on SCADA and Industrial Control Systems Cyber Security Research (ICS-CSR) as well as serving on the editorial board and as reviewer of international journals.

Murray E. Jennex is a Professor of Management Information Systems at San Diego State University, editor-in-chief of the International Journal of Knowledge Management, co-editor-in-chief of IGI Global book series, co-editor-in chief of the International Journal of Information Systems for Crisis Response and Management, and President of the Foundation for Knowledge Management (LLC). Dr. Jennex specializes in knowledge management, crisis response, system analysis and design, IS security, e-commerce, and organizational effectiveness. Dr. Jennex serves as the Knowledge, Innovation, and Entrepreneurial Systems Track co-chair at the Hawaii International Conference on System Sciences. He is the author of over 150 journal articles, book chapters, and conference proceedings on knowledge management, crisis response, end user computing, international information systems, organizational memory systems, ecommerce, cyber security, and software outsourcing. Dr. Jennex is a former US Navy Nuclear Power Propulsion officer and holds a B.A. in chemistry and physics from William Jewell College, an M.B.A. and an M.S. in software engineering from National University, an M.S. in telecommunications management and a Ph.D. in information systems from the Claremont Graduate University. Dr. Jennex is also a registered professional mechanical engineer in the state of California and a Certified Information Systems Security Professional (CISSP), a Certified Secure Software Lifecycle Professional (CSSLP), and a Project Management Professional (PMP).

About the Contributors

Vinita Jindal is an Assistant Professor in the Department of Computer Science, Keshav Mahavidyalaya, University of Delhi since August 2001. She was the Head of Department of Computer Science, Keshav Mahavidyalaya, University of Delhi from June 2017 till May 2019. Before joining the Department of Computer Science, Keshav Mahavidyalaya, University of Delhi, she worked as a Manager/ Sr. Faculty in the PCTI Ltd. from July 1999 to July 2001. She did her Doctorate in Computer Science from University of Delhi in 2018. She did her M.Phil. in Computer Science from Madurai Kamaraj University in 2007, MCA from IGNOU in 2000 and Bachelor in Mathematics from University of Delhi in 1997. She is mainly working in the area of Artificial Intelligence and Networks. Her area of interest includes dark web, deep learning, Adhoc networks, Recommender Systems, Intrusion Detection System, and Vehicular Adhoc networks to name a few.

Kevin Jones is Head of Cyber Security Architecture, Innovation and Scouting at Airbus. He holds a BSc in Computer Science and MSc in Distributed Systems Integration from De Montfort University, Leicester where he also obtained his PhD: A Trust Based Approach to Mobile Multi-Agent System Security in 2010. Kevin has many years of experience in consultancy to aid organisations in achieving accreditation to ISO27001 standard on Information Security Management. He is a recognised expert in Critical National Infrastructure security, SCADA security, and the protection of critical systems. He currently acts as an executive consultant to Airbus on matters of cyber security across multiple domains and platforms and works closely with government agencies on cyber security topics in addition to European programmes such as the “European Control System Security Incident Analysis Network” and the EU Cyber Security Public Private Partnership. He is a frequent public speaker on cyber security and the protection of critical national infrastructure, in addition to an advisor to numerous cyber security research programmes and events. He is a member of the BCS, IEEE, ISACA, and ISC2 and is accredited as a Certified Information Systems Security Professional (CISSP), Certified Information Security Manager (CISM), and ISO27001 Lead Auditor.

Mitch Kajzer is a graduate of the Indiana Law Enforcement Academy class 89-97 and has been in law enforcement since 1989. He holds an Associates Degree in Criminal Justice from Indiana University, a Bachelor's Degree in Psychology from Indiana University, and a Master's Degree in Cognitive Psychology from the University of Notre Dame. He currently works for the Office of the Prosecuting Attorney in St. Joseph County, IN as the Director of the St. Joseph County Cyber Crimes Unit and for the University of Notre Dame as an adjunct professor in the Computing & Digital Technologies Program. Mitch began his law enforcement career with the South Bend, Indiana Police Department. Over the course of his law enforcement career, he held a number of different positions, including road patrol, detective, and traffic crash reconstructionist. Mitch has instructed over 5000 police officers on a number of topics, including officer survival, police action shootings, critical incidents, emergency vehicle operation, accident investigation, computer forensics, technology crimes, Internet investigations, and undercover investigations. In his 30 years in law enforcement, Mitch has been involved in a number of critical incidents, including being shot in the line-of-duty. He has also been awarded the Police Purple Heart and in 1995 was inducted into the American Police Hall of Fame, Legion of Honor. Mitch has been investigating cybercrimes since 2003. He currently holds a number of computer industry technology certifications, including Microsoft Certified Systems Engineer (MCSE), Microsoft Certified Professional with Internet Expertise (MCP+I), A+ Certified Computer Technician, Certified Internet Webmaster – Professional (CIW-P), Certified Computer Examiner (CCE), and Magnet Certified Fo-

rensis Examiner (MCFE). Moreover, Mitch has investigated over 2000 technology-related cases and has conducted over 2500 digital examinations, resulting in hundreds of arrests and convictions. In addition to his work at the Cyber Crimes Unit, Mitch is also an adjunct faculty member at the University of Notre Dame. He currently teaches three undergraduate courses; 1) Introduction to Digital Forensics, 2) Advanced Digital Forensics, and 3) Forensic Psychology – Threat Assessments. Moreover, he conducts research that focuses on constructing algorithms to be used in predictive text analysis on Internet communications of child sexual offenders. Mitch has authored multiple peer-reviewed journal publications and academic conference presentations, both domestic and international, related to the psychology and communications of Internet child sexual offenders. Finally, Mitch also works as a contract trainer for Magnet Forensics Corporation of Waterloo, Ontario. In this capacity, he teaches a number of digital analysis courses throughout the United States to law enforcement and the technology professionals. These include Forensic Fundamentals, IEF Examinations, AXIOM Examinations, Advanced Computer Examination, and Advanced Mobile Forensics.

Ali Kartit is a renowned researcher in the field of information system security at LTI laboratory at ENSA El Jadida. He is involved in research projects in fields related to security & mobility, artificial intelligence applied to security, healthcare & security and research in encrypted data. He is now a full professor at ENSA El Jadida- Chouaib Doukkali University.

Prabhjyot Kaur did B.Sc. Mathematics (Honors) from Jesus and Mary College, University of Delhi in 2015. She did M.Sc. Mathematics (Honors) from LSR College, University of Delhi in 2017. She has interned in Defence Research and Development Organisation for two months and worked on the topic “Cryptography and Cryptanalysis”. Ms Kaur is currently pursuing her one-year Post Graduate Diploma in Cyber Security and Law from University of Delhi.

Puneet Kumar Kaushal has completed his B.Tech and M.Tech in Computer Science and Engineering with specialization in Networks and Security. His research interest included blockchain, cryptocurrency, distributed ledger technology, and decentralized applications and & its security. He has experience of 6 years as Assistant Professor and presently delivering cyber security and cryptography trainings in multiple Universities in north India.

Mayank Kejriwal is a research lead at the University of Southern California’s Information Sciences Institute (ISI), and a research assistant professor in USC’s Department of Industrial and Systems Engineering. He received his Ph.D. from the University of Texas at Austin. His dissertation involved Web-scale data linking, and in addition to being published as a book, was recently recognized with an international Best Dissertation award in his field. His research is highly applied and sits at the intersection of knowledge graphs, social networks, Web semantics, network science, data integration and AI for social good. He has contributed to systems used by both DARPA and by law enforcement, and has active collaborations across academia and industry. He is currently co-authoring a textbook on knowledge graphs (MIT Press, 2018), and has delivered tutorials and demonstrations at numerous conferences and venues, including top academic venues such as KDD, AAAI, and ISWC, and industrial venues. He is currently serving as general chair of the ACM K-CAP conference in 2019, and is co-editing a special issue on knowledge graphs in the Semantic Web Journal. He was awarded a Key Scientific Challenges award in 2018 by the Allen Institute for Artificial Intelligence, and was recently named a Forbes Under 30 Scholar.

About the Contributors

Nasreen Khan is a senior lecturer in the Faculty of Management, Multimedia University, Malaysia. She received her PhD from University Malaya in 2012. She has been an academician for over ten years and was involved actively in teaching, research, and supervision. Her publications have appeared in various international refereed journals and conference proceedings. Her research interests include service marketing, technology marketing, marketing communication, consumer behavior and human resource management.

Shereen Khan is a Lecturer and Unit Coordinator at the Law Unit, Faculty of Management, Multimedia University. She obtained her LLB (Hons) Degree from the International Islamic University, Malaysia and completed Master in Comparative Laws from the same University and admitted as an advocate and solicitor at the High Court of Malaya. She obtained her Doctorate from the National University of Malaysia. Her area of research for the Ph.D was on the Company Law, in particular on corporate insolvency. Dr. Shereen Khan's main research interests are on Company Law, Business Law and Cyber Law. She lectures on Company Law, Business Law and Cyber Law at the Faculty.

Tehmina Khan is an academic at RMIT, School of Accounting, Melbourne, Australia. She has published widely in the area of sustainability (social and environmental) accounting and accountability.

Michael Kiperberg was born in Ukraine, in 1987, and migrated to Ashkelon, Israel. He received B.Sc. and M.Sc. degrees in Computer Sciences from the Tel Aviv University, Israel, in 2009 and 2012, and his Ph.D. degree from the University of Jyväskylä, Finland. Michael is currently holding a position of a lecturer at the Holon Institute of Technology (HIT), Israel. Michael's research interests include virtualization and security.

Marcos Paulo Konzen is a Lecturer at the Federal Institute of Science, Education and Technology Farroupilha (IFFar, Alegrete, RS, Brazil). He holds BS degree in Informatics from the Methodist College of Santa Maria (FAMES, Brazil, 2009), MSc (2012) degree in Production Engineering from the Federal University of Santa Maria (UFSM, Brazil). Cisco Certified Network Associate (CCNA) Instructor. His primary research interests include software-defined networking and network security.

Muhammet Köroğlu has been an Assistant Professor at Uşak University, Faculty of Economics and Administrative Sciences, Social Work Department. He obtained his Master's Degree from Selçuk University Philosophy and Religious Sciences Department in 2004. And he obtained his PhD from Necmettin Erbakan University in 2012. He focused on relations of public sphere and religion in his PhD researches. His research interests are social and religious movements, social work with elderly and relations of autonomous public spheres, and religion.

Ana Lambrecht is a lawyer. Investigator Institute of Public Politics and Government of the National University of Río Negro (UNRN).

Mufutau Lamidi is Professor of Generative Syntax and Contact Linguistics at the University of Ibadan, Nigeria. His research interests include Syntax, Contact Linguistics, Sociolinguistics, Applied Linguistics and Media Studies. He has written books and several journal articles which are published in reputable outlets locally and internationally.

Roe Leon finished his MSc in Software Engineering in JYU at 2016 and his PhD at 2019. Roe researches the field of applications of hypervisors in security.

Leandros A. Maglaras received the B.Sc. degree from Aristotle University of Thessaloniki, Greece in 1998, M.Sc. in Industrial Production and Management from University of Thessaly in 2004, and M.Sc. and PhD degrees in Electrical & Computer Engineering from University of Volos, in 2008 and 2014 respectively. In 2018 he was awarded a PhD in Intrusion Detection in SCADA systems from University of Huddersfield. He is the head of the National Cyber Security Authority of Greece and a part time Senior-Lecturer in the School of Computer Science and Informatics at De Montfort University, U.K. He serves on the Editorial Board of several International peer-reviewed journals such as IEEE Access and Wiley Journal on Security & Communication Networks. He is an author of more than 90 papers in scientific magazines and conferences and is a senior member of IEEE.

Roberto Marmo received the Laurea (cum laude) in Computer Science from Salerno University (Italy) and Ph.D. in Electronic and Computer Engineering obtained from the University of Pavia (Italy). He is presently contract teacher of computer science at Faculty of Engineering of Pavia University, Italy. His most recent work is concerned with mathematical models and software for social network analysis. He is author of “Social Media Mining”, a textbook in Italian language on help extraction of business information from social media, website <http://www.socialmediamining.it>.

Anuradha Mathrani is a senior lecturer in Information Technology in the School of Natural and Computational Sciences at Massey University, Auckland, New Zealand. Her research interests include software quality and reliability measurements, distributed software architectures, application lifecycle management, technology enhanced teaching/learning practices and e-commerce governance methods.

Rande W. Matteson retired in 2006, as a Senior Supervisory Special Agent (Federal Agent) after a 32-year law enforcement career having served in responsible international and domestic leadership-management and field and special covert assignments. During his career, Matteson served in various special project assignments and as an Agency Commander at the 2001 Winter Olympics in Salt Lake City, UT. Matteson had diplomatic assignments in Latin America, the Middle East-Asia and domestically. He served in the Leadership Unit at the FBI-DEA Academy and HQTS as a Manager-Supervisory Special Agent. Matteson has been qualified as an expert witness in federal courts and is a subject matter expert (SME) in many varied aspects of crime. In addition, he is certified as a fraud examiner, hostage negotiator, and in maritime security and a physical fitness coordinator. He has completed numerous Marathons and international and domestic Ironman and Sprint distance triathlons. He is a faculty member at Nova Southeastern University serving as a doctoral dissertation mentor and teaches graduate courses in leadership. Previously, he served as an Associate Professor (Department Chair) in the Department of Criminal Justice Flagship Program. He developed and taught undergraduate and graduate classes in law, leadership, economic crime, budgeting, violent crime, terrorism, ethics, criminal investigation, and fiscal management. He holds membership in over 12 professional organizations and has participated-served on 25 various academic committees. He has authored over 25 scholarly publications, numerous textbook chapters, and several books. He frequently presented various subject matter topics at many domestic

About the Contributors

and international venues and faculty colloquiums. In addition to his scholarly publication record, he has served as an editor and on research committees for scholarly publications. His scholarly interests include complex global social and societal justice issues tied to dysfunctional leadership.

Anita W. McMurtry is an Assistant Professor of Criminal Justice at Atlanta Metropolitan State College. She holds a Ph.D. in Criminal Justice from Capella University, and M.A. in Criminal Justice from Clark Atlanta University. She teaches both face-to-face and online criminal justice courses at the undergraduate level. She also served as a Death Investigation Specialist at Georgia Bureau of Investigation for seven years. Her research interests are juvenile delinquency, juvenile corrections, service oriented programs for youth, and African American issues.

Maria Rosa Miccoli is an expert in Psychology for Well-Being and Behavioral Sciences. Graduated in Psychology for Well-Being with the thesis: “The role of Financial Literacy, trust in Politics and Personality in decision making behavior with effects on long term: a comparison between Italy and Germany” in Milan. She completed one year of internship in the field of behavioral sciences, attending it partially in IULM (Milan, Italy) and partly at the FHWS (Würzburg, Germany).

Vardan Mkrttchian received his Doctorate of Sciences (Engineering) in Control Systems from Lomonosov Moscow State University (former USSR). Dr. Vardan Mkrttchian taught for undergraduate and graduate student’s courses of control system, information sciences and technology, at the Astrakhan State University (Russian Federation), where he was is the Professor of the Information Systems (www.aspu.ru) six years. Now he is full professor in CAD department of Penza State University (www.pnzgu.ru). He is currently chief executive of HHH University, Australia and team leader of the international academics (www.hhhuniversity.com). He also serves as executive director of the HHH Technology Incorporation. Professor Vardan Mkrttchian has authored over 400 refereed publications. He is the author of over twenty books published of IGI Global, included ten books indexed of SCOPUS in IT, Control System, Digital Economy, and Education Technology. He is also has authored more than 200 articles published in various conference proceedings and journals.

Kenrick Mock is a Professor of Computer Science and has worked in the computing field since 1990. He is the author of several textbooks on computer programming, conducts research in intelligent systems, and has served as Associate Dean and Interim Dean for the University of Alaska Anchorage College of Engineering.

Anne-Marie Mohammed is a Lecturer in Economics at The University of the West Indies, St. Augustine, Trinidad and Tobago. She received her Ph.D. degree in Economics from The University of the West Indies, St. Augustine. Her current research interests include industrial economics, economics of regulations, crime and tourism and applied microeconomics.

Sovik Mukherjee is at present Assistant Professor, Department of Economics, Faculty of Commerce & Management Studies, St. Xavier’s University, Kolkata, India. Formerly, Senior Lecturer in Economics, Department of Commerce (Evening; UG & PG) at Shri Shikshayatan College, Kolkata, India. A research fellow in the Department of Economics, Jadavpur University, Kolkata, India. His research interests lie in the areas of applied game theory, applied growth econometrics, energy & environmental economics

and issues related to climate change, socio-health economics, and the econometric analysis of financial crises. He has been awarded with the MOTHER TERESA GOLD MEDAL AWARD_ 2017 for contributions in the field of Economic Growth Research by the Global Economic Progress and Research Association, New Delhi, India. He is a Life Member of the Indian Economic Association (IEA), The Indian Econometric Society (TIES) and the Bengal Economic Association (BEA).

Vinayak Narang has completed his graduation in BSc(H)Chemistry and is currently pursuing Post Graduate Diploma in Cyber Security and Law. He is a people's person who loves to interact with everyone.

Loo Seng Neo is a Principal Behavioural Sciences Research Analyst with the Home Team Behavioural Sciences Centre at the Ministry of Home Affairs, Singapore. For the past 12 years, Loo Seng has been specialising in the area of violent extremism, particularly in the fields of online radicalisation, online threat assessment, pre-attack warning signs, and psychology of violent extremism. He works with a team of research analysts undertaking behavioural sciences research on violent extremism, resilience and intergroup conflict. He has presented at many international conferences, trained law enforcement officers, and published many government research reports and peer-reviewed journals and book chapters on the topic of violent extremism. He has also co-edited a book titled 'Combating Violent Extremism and Radicalisation in the Digital Era' in 2016, and a four-volume compendium titled 'A Behavioural Sciences Approach to Understanding Terrorism' in 2017. Loo Seng is currently pursuing his PhD in psychology researching on the personality profile of violent extremists at Nanyang Technological University.

Eileen O'Donnell was conferred by Dublin City University with an Honours (2.1) BSc Degree in Information Technology and a First Class MSc in Information Systems for Managers. While lecturing on the Post Graduate Diploma in Business Information Systems in the Dublin Institute of Technology a research interest in Technology Enhanced Learning (TEL) commenced. This interest evolved into the pursuit of a PhD through research conducted with the Knowledge and Data Engineering Group, School of Computer Science & Statistics, College of Engineering, Trinity College Dublin, Ireland. Research interests include: cloud computing, virtualisation, green computing, the use of ICT in higher education, instructional design, e-learning, technology enhanced learning, personalised e-learning, user profiling, social networking sites, and human computer interaction.

Liam O'Donnell worked for ten years in the computing industry before commencing employment as a lecturer in the College of Business, Dublin Institute of Technology, Ireland. Liam has lectured in Information Systems for over twenty-five years. He also has responsibility for the management of the computer network for the College of Business. Liam received his BSc in Computer Applications from Dublin City University and his MSc in Computing from Sligo Institute of Technology. Liam's research interests include: Management Information Systems (MIS), Enterprise Information Systems (EIS), cloud technologies, virtualisation, computer networks, Perl and Java programming, fuzzy logic, expert systems, genetic algorithms, Type 1 Diabetes (T1D), social networking sites, instructional design, personalised e-learning, and technology enhanced learning.

Acheampong Owusu holds a PhD in Information Systems from Limkokwing University of Creative Technology, Cyberjaya, Malaysia. He is a Lecturer at the Operations and Management Information Systems (OMIS) Department at the University of Ghana Business School. His research interests include

About the Contributors

Business Intelligence (BI) Systems and Analytics, Technology Diffusion, Cloud Computing, and Ecommerce. Acheampong has published several research articles in peer-reviewed journals. He can be reached at aowusu@ug.edu.gh or owuach@hotmail.com.

Olusola Oyero is a researcher and an associate professor in the Department of Mass Communication, Covenant University, Ota, Ogun state, Nigeria. He has written several articles in international and national journal. He is currently the Head of Department, Mass Communication, Covenant University, Ota, Nigeria.

Suresh Palanimuthu completed PhD at Anna University, Chennai and currently working as a Professor in Galgotias University, Greater Noida, Uttar Pradesh. He has 17 years of teaching experience. He has published more than 25 international journals and contributed book chapters.

Raphael Phan holds the chair of security engineering at the Multimedia University (MMU), having served in British, Swiss & Australian universities prior to his current appointment. He is co-designer of the U.S. NIST SHA-3 finalist BLAKE and has been invited to serve in over 100 peer-reviewed security conferences since 2005. He was the Program Chair of Mycrypt 2016, and General Chair of Asiacrypt 2007 & Mycrypt 2005. He is also the Coordinating Editor of the IOS Press Series in Cryptology & Information Security, and is in the Editorial Board of the Cryptologia journal. He currently guest edits a special issue of the IEEE Transactions on Dependable & Secure Computing with focus on paradigm shifts in cryptographic engineering. Raphael's Erdős number is 2, and h-index at least 31.

Stavros Pitoglou received his BSc in Physics from the University of Patras, Greece in 2000. He currently holds the Chief Technical Officer position in Computer Solutions SA, being responsible for the company's Research and Development activities which include several internal research projects in the fields of Chronic Disease Monitoring, Machine Learning & Artificial Intelligence, Biosignals and Computer Vision & Image Processing. Since 2004 he participated as Project Director or Senior Project Manager in several large-scale projects in the fields of Health IT and Medical Informatics as well as Public Institutions Enterprise Resource Management. His research interests are focused on issues of machine learning and artificial intelligence applications in the healthcare domain, distributed networks and data security-privacy. In addition, he is a PhD candidate in the Biomedical Engineering Laboratory, School of Electrical and Computer Engineering of the National Technical University of Athens.

Bettina Pospisil received the M.A. degree in sociology from the University of Vienna. In 2015 she was Research Assistant with the Institute of Instructional and School Development at the University of Klagenfurt and at the Institute for Information Management and Control at the Vienna University of Economics and Business. Since 2017 she works as Junior Researcher in different KIRAS and FWF funded projects at the Faculty of Business and Globalization at the Danube University Krems. 2017 she and her colleague received the Innovation Award of the Danube University Krems for the project called "CERT-Kommunikation II". By now Bettina Pospisil is the co-author of different papers and presented academic lectures at criminological and technical conferences. Her research interest includes the topics Cybersecurity and Crime Studies.

Christophe Premat is an Associate Professor in French with a major specialization in Cultural Studies at Stockholm University. He is a member of the editorial board of the review *Sens Public*, an international web journal of social sciences. His current research focuses on the perception of participatory processes in the political discourse of French-speaking elites, the analysis of memory debates in France and discourse analysis. He recently published a book on the institutionalization of Francophonie organization (*Pour une généalogie critique de la Francophonie*, Stockholm University Press, 2018) and co-edited in 2015 a handbook on French-German relations, *Handwörterbuch der deutsch-französischen Beziehungen* (Nomos). He is part of the research project analyzing the political discourses in Romance-speaking countries (ROMPOL, Stockholm University) and the research project “Language and power” (*Språk och Makt*, Stockholm University).

Gerald Quirchmayr holds doctoral degrees in computer science and law from Johannes Kepler University in Linz (Austria) and currently is Professor in the Multimedia Systems Research Group of the Faculty of Computer Science at the University of Vienna. In 2001/2002 he held a Chair in Computer and Information Systems at the University of South Australia. He first joined the University of Vienna in 1993 from the Institute of Computer Science at Johannes Kepler University in Linz (Austria) where he had previously been teaching. In 1989/1990 he taught at the University of Hamburg (Germany). His wide international experience ranges from the participation in international teaching and research projects, very often UN- and EU-based, several research stays at universities and research centres in the US, Asia and EU Member States to extensive teaching in EU staff exchange programs in the United Kingdom, Sweden, Finland, Germany, Spain, and Greece, as well as teaching stays in the Czech Republic and Poland. International teaching and specialist missions include UN-coordinated activities in Egypt, Russia and the Republic of Korea. He has served as a member of program committees of many international conferences, chaired several of them, has contributed as reviewer to scientific journals and has also served on editorial boards. He is a member of the Austrian and German computer societies and a member of IFIP working groups. For his contributions to the international IT community he was received the IFIP Silver Core Award in 1995. His major research focus is on information systems in business and government with a special interest in security, applications, formal representations of decision making and legal issues. His publication record comprises approximately 150 peer reviewed papers plus several edited books and conference proceedings as well as nationally and internationally published project reports. In July 2002 he was appointed as Adjunct Professor at the School of Computer and Information Science of the University of South Australia. From January 2005 until January December 2010 he headed the Department of Distributed and Multimedia Systems, Faculty of Computer Science, at the University of Vienna and served as Vice Dean of the Faculty of Computer Science from October 2008 until October 2010. Since January 2011 he serves as deputy head of the Multimedia Systems Research Group group. In 2011 he was appointed as Deputy Director of the Doctoral Studies Programme Natural and Technical Sciences, served as the programs Director from October 2014 until October 2016 and since then again as Deputy Director until October 2018.

Parthasarathi Ramamoorthy received his B.Tech in Information Technology in 2014 under the Anna University, Chennai, India. After graduation, he worked as the System engineer In Tata Consultancy services for more than two and a half years. Currently, he is pursuing Post Graduate diploma in Cybersecurity and law under the Delhi University, India. His main area of focus is on the Issues related to Blockchain and its associated technologies.

About the Contributors

Shalini Ramdeo is a Researcher at The University of the West Indies, St Augustine. Her work focuses specifically on workplace bullying, and organisational justice, with interests in organizational behaviour and organizational development.

Juhani Rauhala is a Research Affiliate and PhD student of cybersecurity at the University of Jyväskylä. He has over ten years' experience in the telecommunications industry, including design and management roles. He has been awarded two patents related to cloud storage. Juhani is a designated Eur Ing by the Federation of European Engineers, and is a senior member of the IEEE. He earned a BScEE (1992) and an MScE (1996) from San Francisco State University. His research interests include the weaponization of ubiquitous technologies and technology abuse.

Tansif ur Rehman has a PhD in European Studies. He has also completed six different Masters in the respective field of Social Sciences, i.e., MA (Economics), MA (International Relations), MA (Philosophy), MA (Political Sc.), MA (Sociology), M.Sc. (Gender & Women Studies). Along with these degrees he has also been able to complete 56 Certification/Credit Courses, 11 Miscellaneous Diplomas, 08 Government of Pakistan Trainings, 04 Certification Courses and Diploma (Languages) - Deutsch, English, Italian, and Russian. He is a Commissioned Class-1 Gazetted Officer, currently appointed as the Head of Sociology department at a respective government institute in Karachi (Pakistan). He is also working on various projects along with working as a Teaching Associate at the Department of Criminology (University of Karachi). He has several publications and has over 18 years teaching as well as 12 years research experience.

Amit Resh was born in Haifa, Israel, in 1959. He received his BSc. in Computer-Engineering and MBA from the Technion, Israel Institute of Technology, in 1986 and 2001 respectively. In 2013 he received his MSc. from the University of Jyväskylä, Finland. In 2016 he received his PhD. from the University of Jyväskylä, Finland. He has more than 25 years of professional experience in hi-tech companies in Israel and the USA. He has previously worked as Program-Manager at Apple and as VP of R&D at Connect One, as well as other companies in the embedded-systems industry. Currently he is COO of TrulyProtect, a startup company developing trusted computing systems based on virtualization technology.

Michael Robinson is a cyber security research engineer at Airbus. As part of the architecture, innovation and scouting team he provides cyber expertise to the business and supports state of the art research into new and novel cyber security solutions. He holds a BSc in Computer Science, an MSc in Computer Security from De Montfort University (UK), and a BA in International Relations from Keele University (UK). He obtained his PhD in cyber security in 2017 from De Montfort University. His research interests include cyber warfare, cyber peacekeeping, cloud security and cyber security risk management.

Nathan J. Rodriguez, Ph.D., is an Assistant Professor in the Department of Communication at Weber State University.

David B. Ross, a professor at Nova Southeastern University, teaches doctoral level courses in educational, organizational, and higher educational leadership. Learning from many perspectives and philosophies from mentors while attending Northern Illinois University, the University of Alabama, and Florida Atlantic University, has assisted him in guiding students in the learning process. Dr. Ross

earned his Doctorate in Educational Leadership, Master of Justice Policy Management with an Executive Certificate in Public Management at Florida Atlantic University, and his Bachelor of Science Degree in Computer Science at Northern Illinois University. Dr. Ross regularly speaks at conferences and provides consultation and training in the areas of leadership and management, policy issues, critical thinking, team building, professional development, academic writing, education, and behavior management. He has written articles and book chapters on leadership, power, narcissism, organizational stress, academic integrity, plagiarism and fraud, entitlement, mobbing/bullying, Gerontechnology, policy development, professional development, and areas of homeland security. Dr. Ross is a co-editor of a book titled Higher Education Challenges for Migrant and Refugee Students in a Global World. Dr. Ross is a dissertation chair and a reviewer for the university's Institutional Review Board. Dr. Ross was named Professor of the Year 2015-2016 for the Abraham S. Fischler College of Education. Dr. Ross is a retired Criminal Investigator/Agent with extensive-applied supervisory and field operations experience involving complex federal, state, local, and international crime; covert-clandestine operative and worked with informants; smuggling, profiling and drug interdiction; public order crime; asset forfeiture, money laundering, and conspiracy; wire and mail fraud; development of evidence for use in sworn affidavits, arrest and search and seizure warrants, pen registers; public and political corruption, technical operations including wire-oral intercepts, high technical human, stationary and aircraft/marine surveillance; intelligence-led programs, and RICO Act crimes.

Fábio Diniz Rossi is a Lecturer at the Federal Institute of Science, Education and Technology Farroupilha (IFFar, Alegrete, RS, Brazil). He holds BS degree in Informatics from the University of the Region of Campanha (URCAMP, Brazil, 2000), MSc (2008) and PhD (2016) degrees in Computer Science from the Pontifical Catholic University of Rio Grande do Sul (PUCRS, Brazil). Cisco Certified Network Associate (CCNA) Instructor. His primary research interests include Fog computing and IoT networking.

Valentina Rotelli obtained a master's degree in Well-being Psychology from the Catholic University (Milan, Italy) and majored in Behavioural Economics and Neuromarketing by cooperating both with IESUM (European Institute of the Human Behaviour Study) and with Catholic University in Milan. She attended an internship at the Faculty of Behavioural and Social Sciences in the field of Health Psychology and Behaviour change and modification, working on a research about the value orientation on reducing the consumption of red and processed meat.

George Saridakis is a Professor of Small Business and Entrepreneurship at the Kent Business School, where he directs the Centre for Employment, Competitiveness and Growth. He is also an Honorary Professor at the University of the West Indies, St. Augustine, Trinidad and Tobago. He received his PhD in Economics from the Institute for Social and Economic Research (ISER) at the University of Essex in 2006.

Melissa T. Sasso is an Italian Canadian native who grew up in Montreal, Quebec. Dr. Sasso attained her Bachelor of Arts in Psychology at Florida International University where she graduated with Cum Laude. She received both her Master's of Science in Exceptional Student Education and Doctorate in Education with a concentration in Organizational leadership at Nova Southeastern University, where she graduated with a 4.0 GPA in both degrees. Dr. Sasso has several years experience working with exceptional students who suffer from disabilities from Pre-K to grade 5 and is still interested in remaining within the education field. She has written articles with her Dissertation chair, Dr. David B. Ross, which

About the Contributors

can be found in NSUWorks and has her published dissertation entitled *How Narcissists Cannot Hold an Organization Together: A Mixed Method Approach to a Fictitious Puzzle Factory* located in ProQuest, as well as an international published book chapter within the book, “Chronic stress and its effect on brain structure and connectivity” entitled, “The increase of how mass media coverage manipulates our minds.” Her dissertation received a Dr. Charles L. Faires distinction award. In addition, she is an article reviewer and has also commenced editing various works. Her research interests include stress, and she is a passionate researcher in the fields of toxic workplace environments, narcissistic leadership, as well as academic entitlement.

Chris Scogings is Academic Dean of Information Sciences at Massey University. He is a specialist computer programmer and has been involved in the development of many software applications in order to solve unusual problems. He is an enthusiastic teacher of computer programming and has received the Vice-Chancellor’s award for Excellence in Teaching. His main research interests include computer simulation, artificial life and agent-based modelling.

Walter Seboeck studies political science at the University of Vienna (Dr., Conflict Research) as well as studies at the Vienna University of Economics and Business (Economics), Alaska Pacific University (MBA, Telecommunications Management) and at the Danube University Krems (MAS, MSc, Telematics Management). Presently Assistant Professor of Security Studies. Since 2001 he is head of the Center for Infrastructure Security at Danube University Krems. From 2009 to 2015, he was Head of Department for E-Governance and responsible for the development and expansion of the Department. From 2011 to 2012, he was Founding Dean and responsible for the development, structuring and establishment of the Faculty of Business and Globalization. In all areas and organizational units he was responsible for, research activities and agendas were founded and sustainably developed. From 2011 to 2013, as interim Head of Department of Economics, he was responsible for renovation and restructuring of the Department of Economics as well as for the Department’s expansion by a research area. From 2010 to 2013 he was a member of the Academic Senate of the University. Within the Senate, he headed the committee for honors (for services to the University) and was a member of the Curricular Commission. Seboeck is publisher of the *Journal of E-Democracy and Open Government (JeDEM)* and publisher of the conference proceedings for the annual Security Conference Krems (SiKo). He is a lecturer on information security and change aspects in the Digital Economy at Lomonosov University in Moscow, Hebei Finance University and Xingtai University in China.

Jamie Segerson is currently working in the field of Speech-Language Pathology. She received her Master’s Degree in Speech-Language Pathology from Wayne State University in 2019. Before beginning her Master’s program, Jamie spent two years working as an AmeriCorps literacy tutor in Washington, DC. She graduated from the University of Notre Dame in 2014 with a BBA in Management Consulting and a secondary major in Psychology and is originally from Dearborn, Michigan.

Soonhwa Seok holds a Ph.D. in curriculum and instruction. Her research foci include assistive technology and the digital literacy of students with autism, intellectual, and developmental disabilities. She has conducted extensive research in the area of behavior interventions using single case design. Complementing her research interests, she serves as a reviewer for a number of journals, to include *Educational Technology Research and Development* and the *British Journal of Educational Technology*.

Manisha Shahi completed her B.Sc Physical Science (Computer Science) from Maitreyi College, University of Delhi. She is currently pursuing her Post Graduate Diploma in Cyber Security and Law from Institute of Cyber Security and Law, University of Delhi.

Murad Al Shibli Associate Professor, has completed his Ph.D. in 2006 from Concordia University in Canada. Working as the Head of Autonomous and Artificial Intelligent Systems at Abu Dhabi Polytechnic in UAE as well as the Project Manager of Joint Aviation Command Program (JAC). Holds more than 25 years of industrial and academic experience in Canada, Jordan and UAE, at Concordia University, German Jordanian University, American University of Sharjah, UAEU University, and Abu Dhabi Polytechnic affiliated with Institute of Applied Technology. Established new programs in AI, Autonomous Systems, Electromechanical Engineering Technology and Mechatronics Systems. Worked as the chair of the Mechatronics Program at German Jordanian University. Published more than 50 publications in international journals and conferences. Registered 6 provisional patents in USA, filed two non-provisional patents at US Patent Office, and having two patents have been approved by TAKAMUL in UAE. Active researcher in AI systems, neural networks, machine learning and big data, robotics, autonomous systems, drones, anti-drone systems, control systems, mechatronics, space systems, and technical education paradigm.

Valentina Silvestri is a PhD Student in Experimental Psychology, Linguistics and Cognitive Neuroscience at University of Milano Bicocca (Milan, Italy) and Teaching Assistant in Developmental Psychology (head of the course: Professor Viola Macchi Cassia) at University of Milano Bicocca. Her research interests focus on emotion processing in infants. In particular, in understanding what could be the developmental trajectory in emotion perception. Moreover, attention and perception in developmental disorders, and especially Autism Spectrum Disorder, have always interested her: she graduated in Psychology curriculum Neuroscience with a final dissertation on the experimental project “A correlational study between autistic traits and drawing in children: evidence of a distributed fine-grained analysis”. She worked as research assistant at Basque Center on Cognition, Brain and Language (BCBL) in San Sebastian – Donostia (Spain) working on neuropsycholinguistic processes and ERPs and at Instituto Universitario de Neurociencia (IUNE-Neurocog) at University of La Laguna in Tenerife (Canary Island) participating in a project on neurostimulation in ASD subjects.

Riann Singh is a Lecturer in HRM at The University of the West Indies, St. Augustine, Trinidad. She has done independent and joint research on HRM in SMEs, the predictors and the darker side of embeddedness/workplace deviance, employee engagement and tourism perceptions. She has published works in The International Journal of Human Resource Management, The International Journal of Human Resource Development and Management, The Journal of Business Leadership, The Global Encyclopaedia of Public Administration and Public Policy, The Journal of Eastern Caribbean Studies, Caribbean Teaching Scholar, among other journals.

Martin Steinebach, born 1971 in Hanau, studied computer science at the TU Darmstadt from 1992 to 1999. In 1999 he became a PhD student at the GMD IPSI, in 2003 he received his PhD in Computer Science at the TU Darmstadt with a thesis on digital audio watermarks. In 2007, following the dissolution of IPSI, he moved to SIT, where he became head of the Media Security and Forensics department in 2010. Since November 2016, he has been an honorary professor at the TU Darmstadt, where his lectures include multimedia security. He is the author of over 170 publications. With his work on the ForBild

About the Contributors

project, Mr. Steinebach and his colleagues achieved second place at the IT Security Award 2012 of the Horst-Görtz Foundation. He leads numerous projects on IT forensics and big data security for industry and the public sector.

Larry Stewart currently serves as Executive Director and Associate Professor of Criminal Justice within the Criminal Justice and Police Sciences Program at Atlanta Metropolitan State College, Atlanta, Georgia. Prior to his current positions, he served as Associate Professor of Criminal Justice within the Criminal Justice Program at Savannah State University, Savannah, Georgia. He also served as Associate Professor and Program Coordinator for the Master's Degree Program in Public Safety Leadership within the Department of Leadership Studies, College of Continuing and Professional Studies at Mercer University, Macon, Georgia. He served as Dean, College of Public Safety Administration, St. Petersburg College, St. Petersburg, Florida, and Department Chair, Urban Affairs, Social Sciences & Social Work, University of the District of Columbia, Washington, DC. He holds the Doctor of Philosophy in Public Administration from the University of Southern California, Los Angeles, California.

Olivia Swee Leng Tan was a Legal Counsel of Kuala Lumpur Regional Centre for Arbitration (KLRC) and in charge of the Domain Name Dispute Resolution for both .com from Asian Domain Name Dispute Resolution Centre and .my cases at KLRC, as well as Mediation/Arbitration case management. She obtained her Bachelor of Law Degree with honours in 1993 from University of London (UK) and completed her Certificate of Legal Practise (CLP) in 1996. She was the book prize winner for the Civil Procedure Paper and General Paper awarded by the Certificate of Legal Practise Board (Malaysia) in 1996. She practised as an advocate and solicitor in Malaysia in the area of Corporate Litigation, Intellectual Property (Trademark), and Banking and Conveyancing. She continued to pursue her Masters in Law at the National University of Malaysia (UKM) in 2002. She obtained her PhD in Law at the National University of Malaysia (UKM) in 2014. Presently, she lectures Business Law, Corporation Law, Law for Engineers, Cyber Law, Media Law, Legal Informatics for Managers and Industrial Relations Law and also serves as the Director for Collaboration and Innovation Centre at Multimedia University (MMU) Malaysia.

Daniel Chaves Temp is a Lecturer at the Federal Institute of Science, Education and Technology Farroupilha (IFFar, Alegrete, RS, Brazil). He holds BS degree in Informatics from the University of the Region of Campanha (URCAMP, Brazil, 2009) and Specialization (2018) in Computer Networks. Cisco Certified Network Associate (CCNA) Instructor. His primary research interests include network security and management.

Poongodi Thangamuthu completed Ph.D at Anna University, Chennai and currently working as an Assistant Professor in Galgotias University, Greater Noida, Uttar Pradesh. She has 12 years of teaching experience in the field of computer science. Her area of interest lies in the field of Internet of Things, Big data, Blockchain, Networking. She has published more than 10 international journals and contributed book chapters.

Ciza Thomas is currently working as Senior Joint Director, Directorate of Technical Education, Government of Kerala, Trivandrum, India. She completed her B.Tech and M.Tech from College of Engineering Trivandrum and PhD from IISc, Bangalore. She was trained in Cyber Security at the Com-

puter Emergency Response Team (CERT) at US and also at Carnegie Melon University, Pittsburgh, US under Govt. of India scholarship. Her area of expertise is Network Security with research interest in the fields of Information Security, Data Mining, Sensor Fusion, Pattern Recognition, Information Retrieval, Digital Signal Processing, and Image Processing. She has publications in more than 40 International Journals and International Conference Proceedings. She has edited five books in the field of Sensor Fusion, Complex Systems, Data Mining and Ontology. She has published seven book chapters in the field of network security and pattern recognition. She is a reviewer of more than ten reputed International journals including IEEE transactions on Signal Processing, IEEE transactions on Neural Networks, International Journal of Network Security, International Journal of Network Management, and IEEE-John Wiley International Journal on Security and Communications Network. She is a guest editor of the IEEE Security and Privacy Magazine. She is a recipient of achievement award in 2010 and the e-learning IT award in 2014 from Government of Kerala.

Sachin Tiwari is doctoral candidate at the Centre for Canada, US and Latin American Studies (CCUS&LAS) at School of International Studies, Jawaharlal Nehru University (JNU), India. His research interest includes working on the issues of international relations, global governance particularly cybersecurity and its implications on security. He completed his M.A. in Political Science from Jamia Millia Islamia University, New Delhi, India. Later he completed his M.Phil. on dissertation titled 'US Search for Cybersecurity: Domestic and International Dimensions' in 2018 from JNU. He has published conference papers, articles and book chapters on topics prominently Contestation in Cyberspace and International relations, Cyber Policy, and aspects of US Foreign policy.

Curtis L. Todd is a professor of Social Work at Atlanta Metropolitan State College in Atlanta, Georgia, USA. His research and practice interests include child and family welfare, adult learners and distance education, first generation college students, retention and college completion programming. Other areas of scholarly inquiry include restorative justice, incarceration disparities and social control mechanism within criminal justice systems. He received his Western education, training and advanced degrees from Clark Atlanta University (Ph.D., Social Work Policy, Planning, Administration, and Social Science), the University of Georgia (M.S.W., Social Work) and Albany State University (M.S., Criminal Justice).

Deepak Singh Tomar obtained his B. E., M. Tech. and Ph. D. degrees in Computer Science and Engineering. He is currently Assistant Professor of CSE department at NIT- Bhopal, India. He is co-investigator of Information Security Education Awareness (ISEA) project under Govt. of India. Currently, he is chairman of cyber security center, MANIT, Bhopal. He has more than 21 years of teaching experience. He has guided 30 M Tech and 3 PhD Thesis. Besides this he guided 70 B Tech and 15 MCA projects. He has published more than 54 papers in national & international journals and conferences. He is holding positions in many world-renowned professional bodies. His present research interests include web mining and cyber security.

Zafeiris Tsiftzis (Ph.D, LL.M., BSc) is currently working as a legal advisor in UK civil litigation. He has already completed his doctoral studies in International Human Rights Law in the School of Law at the University of Bolton (Bolton, United Kingdom). His research interests are based on human rights law and humanitarian law and also on international law and international criminal. His doctoral research is on the international preventive framework for human rights abuses committed by private military and security companies.

About the Contributors

Pasi Tyrväinen is a Professor of Information Systems and the Dean of the Faculty of Information Technology at University of Jyväskylä. His background includes fourteen years at Honeywell and Nokia Research Center. He has 100+ publications on software business, enterprise content management, artificial intelligence, technology adoption etc. in EJIS, IST, JIE, JIM, JSS, DSS, IEEE Software and others.

Rizwan Ur Rahman obtained B.E and M.Tech in Computer Science from Maulana Azad National Institute of Technology (MANIT), Bhopal with Hons grade. His programming experience includes C/C++, C#, SQL, ASP, ASP.NET, VB, VB.NET; Win Forms, Web Forms and Java. He has worked on government projects and R&D department of CRISP. Currently he is an assistant professor in JayPee University, Solan, H.P., India . His area of research includes web programming and web security.

Rossanne Gale Vergara is currently a PhD candidate at Multimedia University, Malaysia. Her research area is in biometric data security regulation and policy. She obtained her Master of Business Administration “Multimedia Finance” from Multimedia University in 2018 and her Bachelor of Science in Oceanography from the United States Naval Academy in 2004.

Rishu Verma is B.Tech Student at JayPee University, Solan, India.

Michael Villano provides research computer consulting to the Department of Psychology at the University of Notre Dame. He is also the Assistant Director of the eMotion and eCognition Laboratory where he conducts research in human robotic interaction and applications of video game and robot technology to a variety of health and social issues. Current projects include investigating moral decision-making of drone pilots in a simulated 3D game environment with the United States Air Force Academy and the development and validation of a 2D game-based cognitive assessment tool for the United States Air Force School of Medicine. Dr. Villano is also the Co-Director of the Virtual Reality Laboratory where he has developed a VR simulation of an on campus building atrium for acrophobia therapy and a shopping mall for the study of prospective memory. Prior to returning to the academic environment, Dr. Villano conducted research and development for various industries in e-commerce, web-based electronic performance support systems, human-computer interaction, ergonomics and computer-based simulation and training.

Danish Wadhwa is B.Tech Student at JayPee University, Solan, India.

Lacey Wallace is an Assistant Professor of Criminal Justice at Penn State Altoona. Her research focuses on juvenile delinquency and substance use. Her work also includes an examination of family and peer processes that contribute to these behaviors.

Ping Wang is a Professor of Computer and Information Systems at Robert Morris University and a Certified Information Systems Security Professional (CISSP). He is also a Sun (Oracle) Certified Java Programmer and has over 10 years of consulting experience in Information Technology, E-Commerce, Cybersecurity, and served as a senior developer on a US Department of Defense grant project on Survivability and Information Assurance for three years. Dr. Wang has over 20 years of experience in teaching, research, curriculum development, and program management in higher education including most recently serving as Program Director and Professor of Cybersecurity in the University of Maryland system.

He has received three best paper awards for his publications on Cybersecurity at recent international conferences in addition to several other distinguished national and international awards for innovation, teaching, and research.

Veronica Wegner is a Neuroscience and Behavior Pre-Health Major, University of Notre Dame Class of 2019.

David Wesley is a lecturer and case research manager at Northeastern University's D'Amore-McKim School of Business, Department of International Business and Strategy. His research encompasses a range of strategic management topics, including international strategy, cultural diversity, intellectual property, and new product development. He has published more than 100 case studies and is co-author of *Innovation and Marketing in the Video Game Industry*.

Jessica Whitney earned her Masters of Science in Information Systems and Bachelors of Science in Marketing from San Diego State University where she was recognized as 2017's Most Outstanding MSIS graduate. She has received multiple awards for her thesis research which focused on the use of technology and knowledge management principles to help identify online human trafficking and the design of a decision support system for the effective response to technology-driven insight in this field. During her graduate studies, Ms. Whitney also worked as a Graduate Assistant in the Management Information Systems department at SDSU. She started her professional career with the County of San Diego in 2014 supporting the technology used by attorneys, support staff, and investigators in their pursuit to protect the innocent and prosecute the criminals. She has recently accepted a position working with law enforcement on data management and analytics.

Michelle F. Wright is a research associate at Pennsylvania State University. Her research interests include the contextual factors, such as familial and cultural, which influence children's and adolescents' aggression and victimization as well as their pursuit, maintenance, and achievement of peer status. She also has an interest in peer rejection and unpopularity and how such status relate to insecurity with one's peer standing, aggression, and victimization.

Szde Yu is an Associate Professor of Criminal Justice at Wichita State University. His specialization area includes cybercrime and computer forensics.

Nezer Zaidenberg completed his B.Sc (1999 CS and operations research), M.Sc (2001, Operations research) and MBA (2006, finance) from Tel Aviv University. Nezer completed his PhD in the university of Jyväskylä, Finland. (2012, faculty of IT) Nezer was awarded Docent from the university of Jyväskylä in 2013. Nezer was software engineering faculty member in Shenkar college, Israel and is currently a CS faculty member in the college of management academic studies, Israel. Nezer is also leading Truly-Protect a start-up developing hypervisor-based security solutions.
